PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-31
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1978.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

5365 THE MORPHOLOGY OF THE PAPILLA OF VATER. (Ger.) Fodisch, H.-J. (No affiliation given). *Fortschr. Med.* 93(5):193-197; 1975.

The morphology of the papilla of Vater is reviewed. In many respects the papilla of Vater serves as the keystone of a functional system including the duodenum, bile ducts, liver, and pancreas. Aside from the variations in filling and emptying conditions, variations in form result only from the inclination of the opening plane, which may be vertical or inclined at various angles. Obstacles that may interfere with endoscopic recognition of the papilla are major positional anomalies and confusion with duodenal polyps or ancillary papillae, enlarged hoods covering the organ, large longitudinal mucous membrane folds, and openings of the ducts in or on the edge of large duodenal diverticuli. The mucous membrane of the papilla contains a system of duplicatures and niches, varying from longitudinal folds at the bottom, to a network structure in the center, and a band functioning as a valve at the upper end. The normal microscopic picture of the papilla has been the subject of controversy, but cross sections of the organ reveal a layered structure. The form and function of the gland are closely interrelated. The superficial and glandular epithelium is monolayered and cylindrical, and produces neutral and acidic mucopolysaccharide mixtures. The helical musculus complexus papillae serves secretion transport, and the valve system of the mucous membrane prevents reflux and duodenal influx. The nervous and neurohormonal regulation of papillar function remains unresolved. Two symptomatic findings are important for the endoscopist: uniform enlargement of the structure and structural deviations of the opening. The benign stenosis syndrome is generally due to chronic granulating inflammation. Florid papillitis was found in 84.5% of acute and chronic duodenal ulcers in the papillar area, in 93.6% of cases with choledocholithiasis, and in 65% of the cases of cholelithiasis and chronic cholecystitis. Smear, curettage, and biopsy examination methods may each be useful.

5366 THE STRUCTURE AND HISTOCHEMICAL FEATURES OF HUMAN VATER'S PAPILLA MUCOSA (BASED ON AIMED BIOPSIES). (Rus.) Aurin, L. I.; Vasiliev, Y. V.; Gorodinskaja, V. S.; Malkerova, N. N. (Res. Inst. Gastroenterology, Moscow, USSR). *Arkh. Anat. Gistol. Embriol.* 68(3):18-22; 1975.

The structural and histochemical characteristics of the mucous membrane of the papilla of Vater were studied using 5 μ-thick specimens from 52 aimed duodenal biopsies. Three different types of structural and histochemical variations were seen. The first variation, called the duodenal type, did not differ much from the surrounding mucous membrane of the duodenum; it was pink in color, with equally distributed intestinal villi (320-350 μ). A large amount of RNA was detected in the cytoplasm of the cells located in the villi, which gradually decreased toward the top. The cells at the base of the villi contained small granules, which reacted positively with Schiff's reagent, but did not show any coloration with Best's carmine or toluidine blue, revealing the presence of neutral mucopolysaccharide. Histochemically, the duodenal type of membrane variation should be considered to be an absorbent type. The second type of variation was found during 20 autopsies and was called the mucoid type. The membrane was lighter in color and shinier in appearance than the mucous membrane of the duodenum; the villi were short, thick, and irregular (200-250 μ). Cells from this variation should be considered as the secretory type. Epithelial cells resembled the cells of the epithelium of the stomach, bile ducts, and the gallbladder, all of which were colored by Best's carmine. The third type of variation, the intermediate type, appeared to be a not fully differentiated duodenal mucoid form, but appeared capable of becoming either one. In some cases of this variation, the morphologically and histochemically peculiar round form cells were seen, which may be a variation of goblet cells.

5367 DIRECT METHOD FOR ESTIMATING THE TOTAL GASTRIN CELL NUMBER IN THE STOMACH OF RATS. (Eng.) Willems, G.; Nyst, M.; Delince, Ph.; De Graef, J. (St-Peter Hosp., 322 Hoogstraat, B. 1000 Brussels, Belgium). *Gastroenterology* 71(3):533-536; 1976.

A method in which the total number of gastrin cells in the stomachs of small rodents can be directly estimated without measuring the retraction or the total surface is described. By staining the cells with the peroxidase-antibody technique and counterstaining the nucleus, it is possible to correct the nuclear overestimation. In sections of male Wistar rat stomachs, the mean section thickness was 7.2 μm. The mean nuclear diameters of gastrin cells in the cross sections from the strips ranged between 6.4 and 7.0 μm in the six rat stomachs used. The error due to nuclear overestimation was about 92%. The corrected total number of gastrin cells per strip and per stomach ranged between 415,375 and 590,373. Direct counting of the total number of gastrin cells in sections from the entire stomach avoids errors due to tissue retraction and imprecise delineation of the antro-fundic limit. The homogeneity of the values obtained with this technique indicates that it may be used to investigate experimental variations in the total gastrin cell population in the stomachs of small animals.

5368 A LIGHT AND ELECTRON MICROSCOPIC STUDY OF THE CHANGES IN THE DUODENAL MUCOSA INDUCED BY SUSTAINED PENTAGASTRIN STIMULATION OF GASTRIC ACID SECRETION IN YOUNG RATS. (Eng.) Patrick, W. J. A.; Denham, D.; Hawkins, W.; Forrest, A. P. M. (Dept. Clinical Surgery, Univ. Edinburgh, Edinburgh, Scotland). *Br. J. Exp. Pathol.* 56(6):510-522; 1975.

Changes in the duodenal mucosa in young Sprague-Dawley rats, induced by sustained pentagastrin stimulation of gastric acid secretion, were investigated by light and electron microscopy over an 8-week period. Rats received pentagastrin (2 mg/12 hr, s.c.) in a medium of beeswax and mineral oil for up to 8 weeks. Samples of mucosa from the proximal, middle, and distal duodenum were taken weekly. Light microscopy showed that 17 of 24 test animals and 6 of 24 control rats (beeswax and mineral oil only) had a decisive alteration in the villous structure (degenerative epithelial necrosis and edematous bullae). These figures are statistically significant ($0.010>p>0.001$). Under electron microscopy, the villous epithelial cells had separated from the basal lamina and the interval between the cells and the basal lamina was occupied by fine, fibrillary proteinaceous fluid. The epithelial cells were generally enlarged, with the epithelial intercellular space occluded, except for a few limited areas. The plasma membrane of the microvilli showed considerable irregularity and vesiculation. The cytoplasm of the cells was completely disorganized, with fragments of endoplasmic reticulum and Golgi complex, disrupted vacuolated mitochondria, and a variety of pleomorphic membranous vesicles dispersed in a haphazard manner. The goblet cells and the intraepithelial lymphocytes were similarly affected. The basal lamina was at least 10 times thicker than normal; fragments of epithelial cell cytoplasm were attached to its surface. Mucous change was not induced in undifferentiated duodenal epithelial cells. It is concluded that the marked histologic changes are the result of damage to the duodenal epithelium by gastric acid.

5369 INTESTINAL RECOVERY IN THE PIG IRRADIATED AT HIGH DOSES. ENZYMOLOGICAL, HISTOLOGICAL, AND FUNCTIONAL DATA. (Fre.) Daburon, F.; Chomette, G.; Remy, J.; Villiers, P.-A.; Gregond, J.-C.; Tricaud, Y.; Sevignac, M.; Haag, J. (Laboratoire de Radiobiologie Appliquee C.N.R.Z., F 78350 Jouy-en-Josas, France). *Biol. Gastroenterol.* 8(4): 321-338; 1975.

Histological, enzymological, and functional aspects of the intestine were studied in Pitman Moore pigs exposed on the posterior half of their bodies to irradiation with 800-1,500 rads from a ^{60}Co source. When doses were under 1,250 rads, the intestine showed good recovery, histologically and enzymatically, within a month; however, lipid and calcium malabsorption persisted for more than 3 months. Correlation of enzymatic recovery with systematic histological studies of biopsy specimens revealed enzymatic recovery commencing on days 9-10 despite the extent of the histological lesions. Weight of animals exposed to 800 rads remained normal; a weight loss, which was regained in a month, was observed in animals exposed to 950 rads. After exposure to 1,250 rads or more, incipient recovery of the intestine led to permanently atrophic and nonfunctional mucosa and impairment of nutrition.

5370 SUBMICROSCOPICAL STRUCTURE OF GASTRIC MUCOUS MEMBRANE UNDER NORMAL AND PATHOLOGICAL CONDITIONS. I. ELECTRONMICROSCOPIC STUDY OF MUCOSAL SURFACE CELLS AND OF GLANDULAR ISTHMUS CELLS OF NORMAL HUMAN GASTRIC MUCOSA. (Cze.) Belak, M.; Lakata, E.; Bilcik, P.; Kovalkovic, L. ABSORPTION - EXCRETION - TRANSPORT

5380 INTESTINAL ABSORPTION OF VITAMIN D_3, LINOLEIC ACID, AND CHOLESTEROL FROM MICELLAR SOLUTIONS: STUDY IN NORMAL HUMANS BY THE "IN SITU" PERFUSION TECHNIQUE. (Fre.) Lenormand, Y.; Rautureau, M.; Mary, J.-Y.; Rambaud, J.-C. (Hopital Saint-Lazare, 107, rue du Faubourg-Saint-Denis, F 75010 Paris Cedex 10). *Biol. Gastroenterol.* 8(3):207-221; 1975.

The intestinal absorption of vitamin D_3, linoleic acid, and cholesterol from micellar solutions was studied in normal humans (13 men and 4 women, aged 23-67 yr) by the segmental perfusion technique. Mixed micellar solutions contained (per liter of Krebs solution) 10 mM of bile salt conjugated with taurodeoxycholate (TDC) or glycocholate of sodium (GC), 2.4 mM of monooleate, 4.8 mM linoleic acid, 20 µg of vitamin D, 4 µCi tritiated vitamin D_3, 4 µCi of linoleic acid labeled with ^{14}C, 10 g of polyethylene-glycol and 0-4.14 mM/l of cholesterol. Simple micellar solutions did not contain the lipids, linoleic acid or monooleate. The solutions were perfused at a rate of 8 ml/min into a 25-cm segment of the ileum or jejunum. Results were tabulated according to three parameters: (1) level of intestine perfused (jejunal or ileal), (2) the type of bile salt used for micellar solubilization, and (3) the presence of monooleate, linoleic acid and/or of cholesterol in solution. Absorption of vitamin D_3 was significantly ($p<0.05$) lower in the ileum than in the jejunum, although three subjects did not demonstrate this difference. Jejunal absorption of vitamin D was significantly higher with GC than with TDC. Similar results were observed with linoleic acid and cholesterol. Physiological concentrations of cholesterol did not significantly modify jejunal or ileal absorption rates of vitamin D_3 nor did presence of lipids modify ileal absorption of the vitamin.

5381 STIMULATION IN VITRO BY 1,25-DIHYDROXY-VITAMIN D_3 OF INTESTINAL CELL CALCIUM UPTAKE AND CALCIUM-BINDING PROTEIN. (Eng.) Freund, T.; Bronner, F. (Univ. Connecticut Health Center, Farmington, CT 06032). *Science* 190(4221):1300-1302; 1976.

Duodenal tissues from vitamin D-deficient Sprague-Dawley rats were treated with 1,25-dihydroxy-vitamin D_3 [$1,25\text{-}(OH)_2\text{-}D_3$] to determine whether the cell uptake process reflects events *in vivo* and is a metabolic event. The rats were considered to be vitamin D-deficient when they became hypocalcemic (<7 mg Ca/100 ml plasma) or when their intestines contained undetectable amounts of the vitamin D-dependent calcium-binding proteins (CaBP) after being fed a diet containing no vitamin D_2. Rats fed a diet containing 2,200 IU vitamin D_2 per kg served as controls. The calcium uptake of cells isolated from vitamin D-deficient hypocalcemic cells increased with time, and the addition of 4.7×10^{-8} M $1,25\text{-}(OH)_2\text{-}D_3$ markedly and significantly stimulated calcium uptake. This was not the case when a similar amount of 25-hydroxy-vitamin D_3 (25-OH-D_3) was added to the isolation medium. In seven experiments, the addition of $1,25\text{-}(OH)_2\text{-}D_3$ led to an average 2.6-fold increase in calcium uptake in duodenal cells isolated from vitamin D-deficient animals. Cells from vitamin D-repleted animals took up 3.5 times more calcium on the average than did cells from vitamin D-deficient animals. In cells from vitamin D-deficient hypocalcemic animals that had received 15 U (0.39 µg) of 25-OH-D_3 i.p. 30 hr previously, a 3.1-fold increase in calcium uptake was seen over cells from deficient controls. CaBP was found ($V_e/V_o=2$, where V_e is the elution volume, 68 ml, and V_o is the void volume, 34 ml) in the material from the vitamin D-repleted animals, absent in the cells from deficient animals, and present in the $1,25\text{-}(OH)_2\text{-}D_3$-treated vitamin-D deficient animals. The amount of CaBP treated *in vitro* was two-thirds that found in repleted cells, comparable to the increase in calcium uptake. Inhibitors of oxidative phosphorylation (dinitrophenol, methylene blue, potassium cyanide, and dichlorophenol indophenol, all at 5mM) depressed calcium uptake by about half (58, 53, 51, and 49%, resp.), but compounds that bind -SH groups (*p*-chloromercuribenzoate and iodoacetamide, 5mM) had no effect, the inhibition being 6% and 3%, resp. These experiments demonstrate that the cell uptake process is a metabolic event in which $1,25\text{-}(OH)_2\text{-}D_3$ plays a regulatory role.

5382 EFFECT OF PHENFORMIN ON INTESTINAL ABSORPTION OF CALCIUM IN HUMANS.

(Pol.) Jozwicka, E.; Czyzyk, A.; Szymendera, J.; Szczepanik, Z.; Radwan, M. (III Klinika Chorob Wewnetrznych Akademii Medycznej w Warszawie, ul Lindleya 4, 02-005 Warsaw, Poland). *Pol. Arch. Med. Wewn.* 53(6): 535-540; 1975.

The hypothesis that decreased insulin secretion during phenformin hydrochloride treatment is caused by the decreased intestinal calcium absorption was tested in 12 healthy subjects. Feces were collected for three consecutive 4-day periods in six of the subjects, and the calcium content was measured; the first 4-day period was used as a control. During the second period, each member of the group was given three tablets per day, each containing 50 mg of phenformin. During the third period, no drug was given. The remaining six subjects received simultaneously, 10 μCi of Ca^{47}, p.o., and 10 μCi of Ca^{43}, i.v., after which intestinal calcium absorption was determined by deconvolution. This procedure was undertaken both prior to phenformin hydrochloride administration and 6 weeks later, after each subject had received 150 mg of phenformin daily, p.o., for 4 days before the procedure. In both groups, a significant increase in the intestinal absorption of calcium during phenformin administration was observed. Since this drug inhibits the duodenal transport of calcium, the increased absorption was thought to be an effect of increased passive absorption in the more distal parts of the small intestine, facilitated by a slowing down of the motile activity in the small intestine. The results indicate that reduced secretion of insulin caused by phenformin cannot be explained by the inhibition of intestinal calcium absorption.

5383 EFFECT OF SECRETIN ON INTESTINAL MONOSACCHARIDE ABSORPTION AND NET WATER MOVEMENT IN THE RAT.

(Eng.) Bohmer, R.; Rommel, K. (Abteilung fur Klinische Chemie, Universitat Ulm, Steinhovelstrasse 9, D-7900 Ulm, W. Germany). *Digestion* 13(6):325-333; 1975.

The influence of repeated i.v. injections of secretin on the intestinal net water movement and glucose absorption in the rat small intestine *in vivo*, and on the galactose and 3-0-methylglucose uptake *in vitro* was studied in female specific pathogen-free Wistar rats. Catheters were tied into the lumen of the jejunum, 20 and 45 cm distal to the pylorus. This segment was perfused with a solution of glucose (30 mM), Na (147 mM), K (4.0 mM), Ca (2.25 mM), Cl (155 mM), and phenol red (0.02 g/l) at 12 ml/hr for 170 min. Secretin (2.0 clinical U/kg) was administered at 60, 90, and 120 min after the initiation of perfusion. The mean phenol red concentration was 107.37 ± 1.04% for controls and 107.31 ± 1.34% for the secretin group. No significant difference between the two groups could be proved ($p<0.05$). Glucose absorption decreased with increasing perfusion time in both groups. It was reduced by about 0.386 μmol/10 min after secretin administration and 0.410 μmol/10 min in controls. The mean value of glucose absorption in controls (24.5 ± 7.7 μmol/10 min) was not significantly different from that after secretin administration (23.4 ± 7.3 μmol/10 min; $p<0.05$). Galactose uptake showed no significant difference between controls (14.8 mM) and secretin-treated animals (15.4 mM after 5.0 clinical U; $p<0.05$). The maximum volume was 4.33 μmol/ml tissue water/min in controls and 4.23 μmol/ml tissue water/min in secretin-treated animals. Incubation with 3-0-methylglucose gave similar results ($p< 0.05$). The results demonstrate that repeated i.v. injections of secretin (2 clinical U/kg body weight) had no effect on the jejunal glucose absorption and net water movement in *in vivo* perfusion studies of the rat.

5384 INHIBITION OF SODIUM INTESTINAL TRANSPORT AND MUCOSAL (Na^+-K^+)-ATPase IN EXPERIMENTAL FANCONI SYNDROME.

(Eng.) Wapnir, R. A.; Exeni, R. A.; McVicar, M.; De Rosas, F. J.; Lifshitz, F. (North Shore Univ. Hosp., Manhasset, NY 11030). *Proc. Soc. Exp. Biol. Med.* 150(2):517-520; 1975.

The *in vivo* intestinal transport of electrolytes, glucose, amino acids, and (Na^+-K^+)-ATPase was studied in male Wistar rats, following the induction of experimental Fanconi syndrome, to determine whether damage comparable to that in the kidney occurs in the intestinal mucosa. The rats received either 1.5 or 9.0 mmol/kg of 0.15 M maleic acid, i.p., which induced renal alterations similar to those in the Fanconi syndrome. In addition, the intestinal sodium absorption in the maleate-treated animals was decreased from a mean level of 165.8 μEq/min/cm in saline-treated controls to 94.0 μEq/min/cm in animals treated with the lower dose of maleic acid and 51.7 μEq/min/cm in those treated with its higher dose. When the sodium concentration in the perfused buffers was reduced from 140 mEq/l to 78 mEq/l, the absorption of this ion ceased, and a blood-to-lumen secretion occurred at equal rates in animals given maleate or in controls. When the sodium concentration was further reduced to 26 mEq/l, the sodium secretion intensified in controls, but was not further modified in the maleate-treated animals. There was a marked transfer of potassium from the circulation to the intestinal lumen during perfusions with solutions combining intermediate or low sodium levels in the controls. Experimental animals secreted only small amounts of potassium when 78 mEq/l sodium was perfused, and potassium was absorbed when the sodium perfusate was reduced to 26 mEq/l. The (Na^+-K^+)-ATPase activity was decreased from a mean level of 317.2 nmol P hydrolyzed/min/mg protein in controls to 218.5 and 185.7 nmol in animals treated with the lower and higher maleate doses, resp. No changes occurred in the intestinal transport rates of L-lysine, glycine, L-phenylalanine, or α-aminoisobutyric acid perfused separately at 1 mM; similarly, the absorption rates for glucose in buffers, either at 20 or 40 mM, was the same as in controls. The results show that the same effects on (Na^+-K^+)-ATPase occur in the intestinal mucosa as in the kidney after maleate administration. These experiments indicate that only the translocation of electrolytes mediated by (Na^+-K^+)-ATPase is altered. The entry of amino acids into the intestinal cells may not be an energy-dependent process.

5385 SODIUM PUMPS AND GALACTOSE TRANSFER IN THE SHORT-CIRCUITED SMALL INTESTINE.

(Eng.) Ude, J. F.; Barry, R. J. C. (Dept. Physiology, Univ. Ibadan, Ibadan, Nigeria). *Experientia* 32(2):188-190; 1976.

The capacity of the rat jejunum to transfer sodium, and the relation between the electrogenic and neutral sodium pump were investigated, using a short-circuiting technique. When midjejunal sacs were everted and short-circuited in the presence of 28 mM galactose, α-methyl glucoside, or 3-*O*-methyl glucose, the mean net Na transfers (49.9, 52.1, and 53.2 μmol, resp.) were not significantly different from those obtained without added sugar (48.9 μmol). The mean net fluid transfer was 0.13 ml without added sugar and 0.19, 0.21, and 0.16 ml with galactose, α-methyl glucoside, and 3-*O*-methyl glucose, resp. When the sacs were short-circuited in the presence of 28 mM glucose, there was a significant increase in both mean Na transfer (75.9 μmol, $p<0.001$) and in fluid transfer (0.40 ml, $p<0.001$); in the presence of fructose, Na transfer increased to 61.8 μmol ($p<0.01$) and fluid transfer increased to 0.24 ml ($p<0.001$). Galactose, α-methyl glucoside, 3-*O*-methyl glucose, and glucose are actively transferred in the rat jejunum, and all gave rise to an anticipated increase in the short-circuit current. Of the sugars used in these experiments, only glucose and fructose are metabolized significantly by the rat jejunum. It is concluded that under conditions of limited energy sources, the electrogenic Na pump is preferentially used when an actively transferred hexose is present; the neutral Na pump is only able to function when additional energy is available.

5386 IN VITRO INTESTINAL ABSORPTION OF SUGARS IN THE RAT. STUDY OF THE VARIATIONS IN THE CONCENTRATIONS OF ADENYLIC COMPOUNDS AND OF MINERAL PHOSPHATE IN THE MUCOSA.

(Fre.) Rozen, R.; Griffaton, G.; Faudemay, F.; Dupuy, F.; Lowy, R.; Ardouin, B.; Naon, R. (Hopital Bichat, 170, boulevard Ney, 75018 Paris, France). *Ann. Nutr. Aliment.* 29(3):179-199; 1975.

To clarify the energy phenomena that takes place in the enterocytes, the active transport of glucose, fructose, and galactose was studied *in vitro* by the jejunal loop technique in male Wistar rats. Each sugar (10 mM) was incubated with the loop at 37 C for 0-50 min. ATP, ADP, AMP, and inorganic phosphate and protein concentrations were determined in the mucosa. Concentrations of the sugars were determined in the serous membrane and mucosa of the intestine. Results show that sugar concentrations increased constantly in the serous membrane. Glucose and galactose reached a plateau in the mucosal cells; both sugars easily penetrated the enterocyte, however, their exit into the serous cells was delayed. Fructose penetrated the mucosal cells with difficulty, but its exit was easier and became increasingly so throughout the experiment. During the first 10 min of incubation, ATP concentration in the enterocyte fell sharply. After that, the decrease in ATP was related to each sugar; the decrease was linear for glucose, oscillating for galactose, and arrested for fructose. The energy output for the active transport of the sugars was found to be about 40 cal/mol (linear regression coefficient of the ATP time course after the first 10 min). During the first 10-15 min of incubation, the concentration of the inorganic phosphate increased in the mucosal cells and then stabilized. In the case of fructose, this was caused entirely by nucleotide deterioration, while in that of the two actively transported sugars, nucleotide catabolism produced less inorganic phosphate than expected. It is suggested that the active transport of these sugars does not require much energy and that a carrier common to the sugars and the inorganic phosphate may facilitate absorption.

5387 EFFECT OF EXTRINSIC DENERVATION ON ENDOGENOUS NORADRENALINE AND [^{3}H]NORADRENALINE UPTAKE IN THE GUINEA-PIG COLON.

(Eng.) Gabella, G.; Juorio, A. V. (Dept. Anatomy, Univ. Coll. London, Gower St., London WC1E 6BT, England). *J. Neurochem.* 25(5):631-634; 1975.

Because the guinea pig proximal colon contains adrenergic fibers originating partly from intramural neurons and partly from extrinsic neurons of the prevertebral ganglia, the distribution of catecholamines in the proximal colon of guinea pigs was studied. The effect of extrinsic denervation on the catecholamine content was also studied. The colons were removed and dissected into the longitudinal muscle-submuscle-myenteric plexus and the circular muscle-submucous plexus-submucosa-mucosa. No significant difference was observed between different portions of the colon in the content of fluorometrically-determined noradrenalin. Five days after extrinsic denervation, there was a fall in the noradrenalin content in all segments of the proximal colon; in four subdivisions of the longitudinal muscle myenteric plexus (I, II, III, and IV), the mean control levels of noradrenalin were 0.86, 0.97, 0.87, and 0.70 μg/g tissue, resp., while after denervation the levels were 0.23, 0.21, 0.35, and 0.50 μg/g, resp. In the four subdivisions of circular muscle-submucous plexus-submucosa-mucosa, the control levels were 0.70, 1.10, 0.88, and 0.75 μg/g, resp., and after denervation, they were 0.04, 0.01, 0.10, and 0.42 μg/g, resp. The smaller and more variable changes observed in the fourth segment were interpreted as resulting from an incomplete extrinsic denervation, which was due to technical difficulty. In the longitudinal muscle-myenteric plexus, the uptake of tritiated noradrenalin *in vitro* was of similar degree in all segments of the colon in control animals, while in the denervated colon, the uptake was usually less than that in controls. The colons from two control animals were incubated with tritiated noradrenalin and processed for autoradiography in light microscopy. Silver grains appeared mainly on the circular musculature. In the myenteric plexus, the granules were observed both on the connecting strands and on the ganglia. Because denervation caused a nearly complete depletion of noradrenalin in the circular muscle-submucous plexus-submucosa-mucosa, it appears that the intrinsic neurons do not project to the circular musculature, or the submucosa or mucosa.

ABSORPTION - EXCRETION - TRANSPORT

5388 EXPERIMENTAL LYMPHATIC OBSTRUCTION AND FAT ABSORPTION IN THE RABBIT. (Eng.) Planche, N. E.; Hage, G.; Montet, A. M.; Sarles, H. (Unite de Recherches de Pathologie digestive U-31 de l'INSERM, 46, chemin de la Gaye, F-13009, Marseille, France). *Digestion* 13(4):255-258; 1975.

To determine why the increased fecal fat excretion following experimentally induced lymphatic obstruction could not be reproduced in subsequent experiments, the influence of different environmental conditions, treatment for intestinal parasites, season, and diet on fecal fat excretion was studied in 24 rabbits with lymphatic obstruction and 10 controls. Four animals with lymphatic obstruction and two controls received a standard UAR diet supplemented with bread and raw carrots and were followed up for 2-7 months and 15 days to 3 months, resp. Five animals with obstruction and five controls received the standard diet supplemented with raw carrots only, and were followed up for 1-13 months and 2-11 months, resp. Five animals with obstruction and five controls received the standard diet alone and were followed up for 6-14 months and 4-9 months, resp. Nine animals with obstruction and three controls were not given Bifuran for the control of parasites. Three experimental animals and three controls were kept outside from February to July, and the remaining animals were kept in a room at 20 ± 2 C. The fecal fat excretion was not different in controls and animals with lymphatic obstruction. It was not dependent on the different conditions of diet, antiparasitic agents, or temperature, but there were significant seasonal variations; there was a summit in October-November 1968 and September-October 1969, with the lowest values in August 1969. It is concluded that lymphatic obstruction does not modify the fecal fat excretion in rabbits. This is probably due to the importance of the lymphovenous shunts. The different diets, temperature variations, and the use of antiparasitic agents do not explain the discrepancies between the authors' initial results and those presently reported.

MOTILITY

5393 THE EFFECT OF GASTRIN AND SECRETIN ON GASTRIC EMPTYING IN MAN. (Ger.) Meves, M.; Beger, H. G.; Huthwohl, B. (Klinikum Charlottenburg, Freien Universitat, Berlin, Germany). *Z. Gastroenterol.* 13(4):464-467; 1975.

To examine the effect of secretin and gastrin on gastric emptying in man, a ^{51}Cr-labeled meal was administered to 24 healthy test subjects. The movement of the meal from the stomach was measured by analog recording of activity-time curves over the gastric region, using two dorsally and ventrally located scintillation detectors. One group of patients was given an infusion of natural hog gastrin I (2 μg/kg), a second group was given pentagastrin (6 μg/kg), and a third group was given pure natural secretin (75 clinical U). The scintigrams revealed that the fundus/corpus region performs the storage function in the stomach. The rate of gastric emptying in the 30 min prior to gastrin administration was 19.1%; it decreased to 5.0% during the 20-min gastrin infusion, then increased to 10.9% after the infusion was ended. In the pentagastrin group, gastric emptying was decreased from 21.5% during the pre-infusion period to 2.6% during the infusion. In the patients given secretin, gastric emptying decreased from 26.2% in the 30 min before infusion to 5.5% during the infusion. The decrease lasted for an average of 17 min after the end of secretin administration, and the rate of emptying increased to 11.9%. The results support earlier studies, which indicate that exogenous gastrin inhibits gastric emptying, not only by altering the motor conditions in the antrum, but also by way of an increase in duodenal pressure.

5394 GASTRIN INHIBITION OF THE PYLORIC SPHINCTER.

(Eng.) Fisher, R. S.; Boden, G. (Temple Univ. Health Sciences Center, 3401 N. Broad St., Philadelphia, PA 19140). *Am. J. Dig. Dis.* 21(6):468-472; 1976.

Experiments were carried out in 10 normal subjects to determine whether gastrin, administered exogenously as pentagastrin or released endogenously from the antral mucosa, can inhibit the normal pyloric responses to intraduodenal stimuli. Pyloric sphincter pressure increased significantly in response to the intraduodenal instillation of hypertonic amino acids (20 g in 100 ml water), sodium oleate (30 ml), and 0.1 normal concentration HCl (7.6 ml/min), from a basal level of 4.2 ± 0.9 mm Hg to 14.5 ± 1.4 mm Hg ($p<0.01$), 13.3 ± 0.8 mm Hg ($p<0.001$), and 21.1 ± 1.8 mm Hg ($p<0.001$), resp. Duodenal acidification increased pyloric pressure from a resting level of 5 mm Hg to 17 mm Hg. In contrast, the pyloric pressure during i.v. pentagastrin infusion (2 μg/kg/hr) did not significantly change in response to acidification, remaining at 5 mm Hg. During pentagastrin infusion, the pyloric pressure responses were significantly decreased, to 3.4 ± 1.1 mm Hg when HCl was infused ($p<0.001$), to 2.4 ± 1.5 mm Hg when oleate was infused ($p<0.001$), and to 6.2 ± 3.8 mm Hg when hypertonic amino acids were infused ($p<0.05$). Similarly, the intragastric instillation of a mixture of 1.5% glycine (200 ml) and 0.1 normal concentration NaOH (100 ml) resulted in obtunded pyloric responses to these same intraduodenal solutions; pressures were decreased to 5.3 ± 1.5 mm Hg ($p<0.001$) with pentagastrin, 5.7 ± 1.4 mm Hg ($p<0.001$) with HCl, and 4.0 ± 1.5 mm Hg ($p<0.01$) with hypertonic amino acids. Neither pentagastrin infusion alone nor intragastric infusion of glycine and NaOH altered pyloric sphincter pressures from their basal levels. The results suggest that excess serum gastrin concentrations may produce pyloric dysfunction.

5395 A COMPARISON BETWEEN THE EFFECTS OF CERULEIN AND CHOLECYSTOKININ-PANCREOZYMIN ON THE ELECTRIC AND MANOMETRIC ACTIVITIES OF THE HUMAN STOMACH.

(Fre.) Bortolotti, M.; Labo, G. (II^{a} General Medical Clinic and Medical Therapy, Via Massarenti 9, I 40138, Bologna, Italy). *Acta Gastroenterol. Belg.* 38(3/4):111-124; 1975.

The electrical and mechanical activity of the stomach antrum was studied with a suction needle electrode and an air-filled balloon in 23 normal subjects, during and after the i.v. administration of cerulein (15 subjects, 0.5-12.5 ng/kg/min) and cholecystokinin-pancreozymin (CCK-PZ; 8 subjects, 1-8 Ivy dog U/kg/hr). Both substances inhibited electrical and manometric activity proportional to the dose. After administration ceased, there was an increase in electrical and manometric activity above base values. Cerulein was five times as effective as CCK-PZ by weight (3.4 ng/kg/min versus 17.1 ng/kg/min) to obtain a 20% decrease, and the molecular activity ratio was 1.7 (1.352 for cerulein and 3.883 for CCK-PZ). It is known that cerulein and CCK-PZ are also intestinal stimulants (by activation of cholinergic nervous system). However, in this study, their inhibitory effects were dominant. This inhibiting action limits the use of cerulein as a therapeutic agent (e.g., in paralytic ileus), especially if there is gastric ileus.

5396 THE EFFECT OF SECRETIN AND CHOLECYSTOKININ-PANCREOZYMIN ON SMALL INTESTINE MOTILITY IN MAN.

(Ger.) Dollinger, H. C.; Berz, R.; Bargon, G.; von Uexkull, T.; Goebell, H. (Sektion Gastroenterologie, Zentrum fur Innere Medizin, Universitat Ulm/Donau, D-79 Ulm/Donau, Steinhavelstrasse 9, W. Germany). *Z. Gastroenterol.* 13(4):479-481; 1975.

The effects of secretin and cholecystokinin (CCK) on small intestinal motility were examined in healthy volunteers. In the first group of test subjects (four for each hormone), the motor activity of the jejunum was measured using a pressure-sensitive endoradiocapsule. In the second group of five subjects, the transit time of a contrast medium (barium sulfate) from the duodenojejunal flexure to the ileocecal valve was measured by x-ray. In comparison to the control period, the infusion of secretin at 1 U/kg/hr, i.v., resulted in a slight decrease in the number of waves (from 27.6 ± 6.2 for controls to 19.7 ± 6.2), and amplitude index (from 171 ± 53.4 for controls to 100.2 ± 48.3 cm H_2O), the motility index (from 4.2 ± 1.3 for controls to 1.9 ± 0.9), and the percentage of motor activity (from 11.2 ± 2.7 for controls to 5.9 ± 2.1%). The higher dosage of secretin, 2 U/kg/hr, produced a greater (statistically significant) decrease in all four parameters. The number of waves decreased to 7.7 ± 3.4 ($p<0.025$), the amplitude index to 40.2 ± 30.3 cm H_2O ($p<0.025$), the motility index to 0.9 ± 0.8 ($p<0.05$), and the motor activity to 2.3 ± 1.7% ($p<0.0125$). The small intestinal transit time of the contrast medium was shortened by secretin in a dose-dependent manner. CCK, on the other hand, stimulated the spontaneous motor activity of the jejunum. After CCK administration at 1 U/kg/hr, the number of waves increased from 27 ± 2.1 for controls to 36.7 ± 7.9, the amplitude index from 132.3 ± 38.8 for controls to 267.5 ± 84.3 cm H_2O ($p<0.05$), the motility index from 3.0 ± 1.1 for controls to 7.0 ± 2.4 ($p<0.05$), and the motor activity from 9 ± 1.7 for controls to 15.2 ± 4.3%. CCK at 2 U/kg/hr resulted in an increase in the number of waves to 70.1 ± 12.2 ($p<0.025$), the amplitude index to 693.5 ± 275.0 cm H_2O ($p<0.025$), the motility index to 18.4 ± 8.8 ($p<0.025$), and the motor activity of 28.9 ± 7.7% ($p<0.05$). A cholinergic mechanism has been suggested for the action of CCK.

MOTILITY

5397 EFFECTS OF NORMOBARIC AND HYPERBARIC HYPEROXIA ON THE DIGESTIVE MOTILITY OF THE RABBIT. I. ANTRAL-PYLORIC MOTILITY. (Fre.) Santini, R.; Dumas, J.; Peres, G.; Brard, E. (Laboratoire de Physiologie et Pharmacologie, I.N.S.A. Bat 406, 20 avenue Albert Einstein, 69621 Villeurbanne, France). *Soc. Biol. Lyon* 169(6):1534-1542; 1976.

Antral-pyloric electromyograms recorded motility of the pyloric antrum of seven adult male rabbits exposed to hyperbaric and normobaric atmospheres. After implantation of electrodes, animals were exposed to an atmosphere of pure oxygen at either normal (PO_2=673 mm Hg) or elevated (PO_2=1682 or 2592 mm Hg) pressures. Motility of the pyloric antrum was not affected by a normobaric hyperoxia of short duration (20-30 min). There was a notable inhibition of motility when normobaric hyperoxia lasted over 6 hr or during a hyperbaric hyperoxia. This inhibition is independent of the speed at which the pressure is established in the chamber as well as of the time of day.

SECRETION AND METABOLISM

5407 SUPPRESSION OF α-FETOPROTEIN PRODUCTION BY EXTRACTS OF VARIOUS TISSUES. (Eng.) Svet-Moldavskii, G. Y.; Tumyan, B. G.; Karmanova, N. V.; Barkhotkina, M. F. (Acad. Medical Sci. USSR, Moscow, USSR). *Bull. Exp. Biol. Med.* 79(2):171-173; 1975.

The factor that inhibits α-fetoprotein production in newborn rats and mice was studied using the syngeneic serum and 20% extracts of various organs (large and small intestine, liver, kidney, spleen, and striated muscle) of adult BALB/C mice. Extracts were also prepared from the small intestine of 21-day-old mice and from organs of mouse embryos taken during the last days of pregnancy; extracts prepared from whole mouse embryos were also used. Litters of mice were divided into two groups, one of which served as the untreated control; the other group received 0.1 ml of serum or extract, s.c., from the 1st through 4th days of life, 0.2 ml on the 5th and 6th days, 0.3 ml on the 7th day, and 0.5 ml on the 8th and 9th days. In comparison with controls, the α-fetoprotein production in the animals treated with serum or intestine, kidney, or spleen extracts of adult mice was inhibited. The titer of α-fetoprotein in mice treated with serum was 32 versus 512 in controls; 32-64 versus 512 with small intestine; 32-64 versus 256-512 with large intestine; 32-64 versus 256 with kidney; and 64 versus 512 with spleen. In newborn mice treated with the small intestine of 21-day-old mice, the α-fetoprotein titer remained at 64, while the titers in controls were either 128 or 256, depending upon the litter. In newborns treated with liver extract from adult mice, the α-fetoprotein titer was 64, while the titer in controls was 256. In contrast, the titers remained essentially unchanged among controls and newborn mice treated with muscle extract of adult mice or whole embryo extracts. The authors conclude that the α-fetoprotein-inhibiting factor present in adult tissues either acts on α-fetoprotein synthesis in embryonic liver cells or suppresses the proliferation of these cells.

SECRETION AND METABOLISM

STOMACH

5409 DEMONSTRATION OF A CYTOCHEMICAL DIFFERENCE BETWEEN THE TUBULOVESICLES AND PLASMALEMMA OF GASTRIC PARIETAL CELLS BY ATPase AND NPPase REACTIONS. (Eng.) Rubin, W.; Aliasgharpour, A. A. (Medical Coll. Pennsylvania, Philadelphia, PA 19129). *Anat. Rec.* 184(2):251-255; 1976.

Factors that distinguish between the plasmalemma and the tubulovesicles in the gastric mucosa were investigated using cytochemical reactions that have been associated with plasmalemma. Pieces of rat and human gastric mucosa were fixed in glutaraldehyde and paraformaldehyde and were processed for the cytochemical demonstration of ATPase and p-nitrophenylphosphatase (NPPase). Electron microscopy revealed that the ATPase reaction was localized to the plasmalemma and to mitochondrial cristae, and the NPPase reaction was localized to the plasmalemma. The tubulovesicles were unreactive. This cytochemical difference between the plasmalemma and tubulovesicle membrane suggests that the tubulovesicles do not represent an extension of or reserve of mature plasmalemma. If the tubulovesicles represent a reserve of membrane that can be rapidly utilized to expand the plasmalemma, additional membrane constituents are apparently added, activated, or unmasked in the process.

5410 "IN VITRO" MUCIN BIOSYNTHESIS BY HUMAN GASTRIC MUCOSA BIOPSIES. (Eng.) Decaens, C.; Robert, L.; Mignon, F.; Bader, J. P. (Laboratoire de Biochimie du Tissu Conjonctif, Hopital Henri-Mondor, Universite Paris-Val de Marne, Creteil, France). *Biomedicine* 23(9):361-363; 1975.

A functional test of mucin biosynthesis in gastric biopsy samples obtained from four normal human subjects is described. The test involved the estimation of the rate of incorporation of appropriate labeled precursors into secreted and cell-bound mucins. Antral and fundic biopsy samples were incubated for 4 hr with 2 μCi U-^{14}C-glucose (240 mCi/mM). The total protein content (fundus + antrum) of the samples was an average of 800 μg, with no significant difference between the antral and fundic regions. The DNA content of the tissue residues was an average of 30 μg (± 20%). The tissue samples actively incorporated the ^{14}C-glucose from glycoproteins, which was partially released in the medium and partially retained in the tissue residue. The specific radioactivity of both medium (117,250 ± 12,900 counts/min/mg protein) and the tissue residue (137,500 ± 33,700 counts/min/mg protein) were remarkably high, with no distinct differences between the antral and fundic regions. When radioactivity was expressed on both protein and DNA bases, relatively constant results were obtained. These preliminary results are encouraging for the further development of this method.

5411 THE ROLE OF CHOLINERGIC EXCITATION IN THE FORMATION OF HISTAMINE WITHIN THE RAT GASTRIC MUCOSA. (Eng.) Lundell, L. (Dept. Physiology Biophysics, Univ. Lund, Lund, Sweden). *Acta Physiol. Scand.* 97(2):145-149; 1976.

The significance of local cholinergic and long vagovagal reflexes for the formation of histamine was investigated upon distension of the gastric remnant after antrectomy in female Sprague-Dawley rats. In the fasting state, the mean rate of mucosal histamine formation was 4.8 μg/g/3 hr, which was decreased by the administration of atropine (1 mg/kg). Truncal vagotomy was followed by a further decrease in mucosal histamine formation to 2.4 μg/g/3 hr. When unoperated rats received an injection of 2-

deoxy-D-glucose (50 mg/kg) 3 hr before sacrifice, the mean histamine level was 10.9 μg/g/3 hr; this increase was abolished by atropine, which caused the level to drop to 4.6 μg/g/3 hr, and by truncal vagotomy, which made the level drop to 3.2 μg/g/3 hr. Continuous distension failed to affect the rate of histamine formation, whereas intermittent distension was highly effective in the presence of vagal innervation, raising the level to 9.7 μg/g/3 hr, and after truncal vagotomy (7.1 μg/g/3 hr). The failure of continuous distension to increase the rate of histamine formation was presumably due to impaired gastric blood flow, since the mucosa was pale and edematous.

5412 THE MECHANISM WHEREBY GROWTH HORMONE-RELEASE INHIBITING HORMONE (SOMATOSTATIN) INHIBITS FOOD STIMULATED GASTRIC ACID SECRETION IN THE CAT. (Eng.) Albinus, M.; Blair, E. L.; Grund, E. R.; Reed, J. D.; Sanders, D. J.; Gomez-Pan, A.; Schally, A. V.; Besser, G. M. (Dept. Physiology, Univ. Newcastle upon Tyne, Newcastle upon Tyne, England). *Agents Actions* 5(4):306-310; 1975.

The suggestion that the reduction in gastric secretion occurring after the administration of growth hormone-release inhibiting hormone (GH-RIH) could be secondary to a fall in the plasma gastrin concentration was investigated in cats with gastric fistulae. When GH-RIH (10 μg/kg/hr, i.v.) was infused for 1 hr starting 5 min before feeding, the gastric acid secretion was reduced by 96%, but the mean peak serum gastrin concentration 5 min after feeding was not significantly different from controls. When GH-RIH infusion was started 30 min before feeding, the peak serum gastrin was abolished, but the gastrin concentration did not fall below basal levels. Gastric acid secretion remained almost totally inhibited. The mean volumes of gastric juice and food recovered 15 min after feeding were 39.0 ml when the infusion was begun 5 min before feeding and 42.4 ml when the infusion was begun 30 min before feeding. By feeding 15 or 45 min after the end of the 1-hr infusion, no significant reduction of either the immediate prefeeding serum gastrin concentration or the 15-min postfeeding serum gastrin concentration occurred compared with controls. The gastric acid secretory responses were not reduced compared with the control values. There was, however, a significant reduction in the volume of gastric juice and food recovered after feeding when the GH-RIH infusion ended 15 min before feeding (45 ml, $p<0.001$) but not when the infusion ended 45 min before feeding (46.4 ml, $p>0.1$). Since the inhibition of gastrin release is delayed relative to that of acid secretion, the inhibition of food-stimulated acid secretion must occur by a primary effect on the acid secretory mechanism.

5413 COMBINED EFFECT OF GLUCAGON AND CHOLECYSTOKININ ON GASTRIC SECRETION IN MAN. (Eng.) Hendel, L.; Jorgensen, S. P.; Christiansen, J.; Henriksen, F. W. (Glostrup Hosp., Glostrup, Denmark). *Scand. J. Gastroenterol.* 11(Suppl. 37):43-46; 1976.

The question of whether glucagon and cholecystokinin interact in their inhibitory effect on gastric secretion was investigated in seven normal volunteers. Pentagastrin (1 μg/kg/hr, i.v., 2 hr)-stimulated gastric secretion of fluid was inhibited by a mean of 29% when glucagon (20 μg/kg/hr, i.v.) was infused simultaneously. When glucagon was infused in combination with cholecystokinin (0.5 Ivy dog U/kg/hr), secretion was inhibited by 30%, but when cholecystokinin was infused alone, there was only a 14% decrease. The inhibition of gastric acid secretion was slightly more pronounced than the inhibition of fluid secretion, and amounted to 36% with glucagon alone, 44% with glucagon and cholecystokinin combined, and 15% with cholecystokinin alone. The dose of glucagon provoked nausea and sometimes vomiting in all subjects, indicating that this dose may be too large to be within the physiological range. This study did not demonstrate any increased inhibition of gastric acid secretion by glucagon and cholecystokinin. However, the investigation does not exclude the possibility of interaction at lower dose levels as the dose of glucagon may be pharmacological.

5414 THE EFFECT OF ANTRECTOMY ON GASTRIC ACID AND GASTRIN SECRETION. (Eng.) Ashby, D. B.; Himal, H. S. (Dept. Experimental Surgery, McGill Univ., Montreal, Quebec, Canada). *Surg. Gynecol. Obstet.* 141(6):888-890; 1975.

To elucidate the intestinal phase of gastric secretion, experiments were carried out in three Heidenhain pouch dogs to determine if duodenal gastrin is released in response to a protein meal. The ingestion of a meal consisting of 250 g of beef liver plus 400 ml of water resulted in increased pouch acid output and serum gastrin secretion. Acid output began to increase during the first 20-min and peaked at 30 min. Gastrin secretion began to increase at 5 min and peaked at 30 min. When these experiments were repeated following antrectomy and a Billroth I gastroduodenal anastomosis, the acid output did not significantly change from basal volumes in the first 60-min following the test meal. After 60 min, there was a consistent rise, reaching a maximum output of 0.10 ± 0.08 mEq/10 min at 150 min; this persisted throughout the 240-min test period. The serum gastrin levels did not significantly change throughout the test period. The results indicate that antrectomy abolishes the early rise in acid and gastrin secretion in response to a protein test meal. Since gastrin levels did not significantly change throughout the entire experiment, the late increase in acid output must be due to a mechanism other than gastrin release.

5415 EFFECTS OF BY-PASSING THE JEJUNUM ON MUCOSAL SECRETION IN THE PIG. (Eng.) McCance, R. A.; Stoddart, R. W.; Artavanis, C.; Wilkinson, A. W. (Sidney Sussex Coll., Cambridge CB2 3HU, United Kingdom). *Biochem. Soc. Trans.* 4(1):151-154; 1976.

The effects of jejunal bypass on mucosal goblet cell secretion were investigated in 10-day-old Large White piglets by fluorescent-labeled lectins. The bypassed jejunum was dosed at the proximal end and left *in situ*. Small samples of mucosa were removed from the upper and lower thirds of each normal jejunum and from the corresponding parts of the bypassed organs of the experimental pigs soon after death. Duodenal and ileal tissues were also taken. The duodena and ilea of operated animals were almost identical with those of controls. In the normal animals, the lectins showed patterns of staining of the duodenum similar to the upper and lower third of the jejunum. The mucin of the goblet cells was stained with fluorescent-labeled concanavalin A in cells in the lower halves of the villi and crypts. With *Ricinus* agglutinin, they were stained on the sides of the villi, and with fluorescent-labeled aprotinin, they were stained on the sides and especially at the tips of the villi. In the operated animals, the bypassed jejunum showed a reversed pattern of staining, with fluorescent-labeled concanavalin A staining mucin in cells near the tips of the villi, *Ricinus* agglutinin staining a few cells near the crypt, and fluorescent-labeled aprotinin staining the goblet cells generally. In the jejunum of the control animals, Meissner's plexus was extensively stained with fluorescent-labeled concanavalin A, but in that of the operated animals, the plexus appeared to be greatly disorganized in the dilated parts of the blind arm, and was difficult to find. In the duodenum of the operated animals, the plexus was well stained and resembled that of control animals. The results show that fluorescent labeling may form a suitable model for the biochemical investigation of the control of mucin synthesis and its relation to the migration of the intestinal epithelium.

5416 EFFECT OF PYLOROTOMY ON INHIBITION OF GASTRIC SECRETION BY INTESTINAL ACIDIFICATION.

(Eng.) Pober, Z. (Food Sciences Lab., U.S. Army Natick Development Center, Natick, MA 01760). *Am. J. Dig. Dis.* 21(6):448-452; 1976.

Factors involved in the inhibition of gastric secretion by small intestinal acidification were investigated in six dogs with gastric fistula. The gastric secretory response to single s.c. injections of either histamine (0.1 mg/kg) or pentagastrin (6 μg/kg) was measured before and after pylorotomy in each dog. Pentagastrin without acidification produced a mean, peak total acid output, of 19.80 mEq/hr. Intestinal acidification with HCl (0.1 normal concentration) markedly inhibited pentagastrin-stimulated gastric secretion, making the mean peak total acid output 8.89 mEq/hr. The response to pentagastrin without acidification was unaffected by pylorotomy (22.02 mEq/hr), indicating that the stomach was still capable of secreting. Intestinal acidification continued to produce a marked decrease in secretion, even at 24 hr after the surgery (5.87 mEq/hr), indicating that the inhibitory mechanism was still functioning. Similar results were obtained with histamine-stimulated gastric secretion. Intestinal acidification increased the prepylorotomy value from 18.91 mEq/hr to 6.97 mEq/hr; postpylorotomy, acidification increased the value from 21.02 mEq/hr to 14.65 mEq/hr. The results indicate that there is an enterogastric reflex through the myenteric plexus, which controls the inhibitory mechanism.

5417 SECRETION AND IRRIGATION OF GASTRIC MUCOSA DURING DISULFIRAM EFFECT. EXPERIMENTAL STUDY IN THE DOG.

SECRETION AND METABOLISM

Pancreas

5426 ANTIGENIC PROPERTIES OF SUBCELLULAR FRACTIONS FROM CANINE PANCREAS: DEVELOPMENT OF A ZYMOGEN MEMBRANE SPECIFIC ANTIBODY. (Eng.) Mihas, A. A.; Gibson, R. G.; Hirschowitz, B. I.; Ostroy, F. (Div. Gastroenterology, Univ. Alabama-Birmingham, Birmingham, AL 35294). *Proc. Soc. Exp. Biol. Med.* 150(3):618-621; 1975.

A pancreas-specific autoantibody, which is regularly induced in rabbits by immunization with antigenic material prepared from dog pancreatic zymogen membranes, was characterized. The gel electrophoretograms of the zymogen membrane fraction showed only three bands of molecular weight: 62,000, 79,000, and 90,000. All three bands were PAS-positive. Homogenates prepared from dog organs other than the pancreas, including heart, lung, muscle, kidney, adrenal gland, urinary bladder, uterus, esophagus, stomach, small intestine, colon, liver, thyroid gland, parotid gland, and spleen, showed no reaction with the antiserum. The antiserum also failed to react with dog bile and blood serum, pancreozymin-cholecystokinin, secretin, chymotrypsinogen A and B, and gastrin. Pancreatic homogenates from rabbit, rat, guinea pig, and man gave a clear line of precipitation with the antibody. The antiserum failed to react when tested against homogenates of chicken and frog pancreas. When the antiserum was tested against intact zymogen granules and a zymogen granule membrane subfraction, a precipitation line was seen only with the membrane fraction, and no reaction was found with the intact zymogen granules. When the antiserum was tested with lysed zymogen granules, a clear line of precipitation was seen, suggesting that the antigenic properties of the membrane fraction are located in the inner aspect of the zymogen membrane. It may represent glycoproteins of molecular weight 70.000-90,000 as well as smaller species of molecular weight of less than 10,000. The results also demonstrate that the precipitating antibody produced by immunization with antigenic material from dog pancreatic zymogen membranes is organ-specific but not species-specific.

5427 SECRETAGOGUE ACTION OF THE DIBUTYRYL DERIVATIVE OF CYCLIC ADENOSINE MONOPHOSPHATE ON THE EXOCRINE PANCREAS OF THE RAT. (Fre.) Stock, C.; Vincent, D.; Baudin, H. (Unite INSERM N° 61, Strasbourg Hautepierre, France). *Arch. Int. Physiol. Biochim.* 84(2):348-350; 1976.

The stimulatory action of the dibutyryl derivative of cyclic adenosine monophosphate (dbAMP) on the rat pancreas is discussed. The derivative causes an outflow of pancreatic enzymes of the acinus cells. A toxic effect of dbAMP on the exocrine pancreas of the rat is unlikely because an ultrastructural study showed no histological alterations. Metabolic parameters (oxygen consumption, lactic acid, ATP, deoxyglucose transport, incorporation of ^{32}Pi in total phospholipids and phosphatidylmonoinositides) remained unchanged and the secretory stimulation was constant and reversible. As the secretagogue effects of dbAMP were not inhibited by antimuscarinic, antinicotinic, and antiadrenergic agents, mediation by a neurochemical agent is also unlikely. An interaction of dbAMP with the exocrine acinus cell is supported by the endergonic character of the secretagogue action, its calcium dependence, and the inhibition of the action by cytochalasine B. The relative need for energy suggests that this interaction may take place at the level of the final steps of the secretory cycle involved in exocytosis.

5428 PANCREATIC ENZYME RESPONSE WITH AN ELEMENTAL DIET. (Eng.) Neviackas, J. A.; Kerstein, M. D. (Veterans Admin. Hosp., West Haven, CT). *Surg. Gynecol. Obstet.* 142(1):71-74; 1976.

The effects of chemically defined or elemental diets on the pancreas were investigated in six mongrel dogs. Dogs were maintained on a regular chow diet, switched to an elemental diet (Vivonex-100), and subsequently returned to the chow diet. To study the pancreatic enzyme response to the diets, each dog had had a chronic duodenal cutaneous fistula with a Thomas cannula inserted opposite the main pancreatic duct. Pancreatic juices were collected in 15-min samples and tested for pH, volume, lipase, amylase, and trypsinogen. The pH for all samplings was 9.0. The lipase values averaged 2,200 with the regular diet and 1,300 with the elemental diet. After returning to the regular diet for 1 month, the lipase returned to pre-elemental diet levels. The amylase level averaged 180,000 Somogyi U with the regular diet, but dropped to 40,000 Somogyi U after 1 month on the elemental diet; it also returned to regular diet levels after 1 month on the regular diet. The trypsin level fell from 3,000 to 700 mU on the elemental diet and returned to normal levels with a regular diet. The enzyme output could be increased slightly by increasing the amount of the elemental diet. These data provide evidence that chemically defined diets may be malabsorbed. It supports the previously reported observation that elemental diets have increased calorie requirements.

5429 AN IN VITRO EVALUATION OF POSSIBLE CHOLINERGIC AND ADRENERGIC RECEPTORS AFFECTING PANCREATIC AMYLASE SECRETION. (Eng.) Williams, J. A. (Dept. Physiology, Univ. California, San Francisco, CA 94143). *Proc. Soc. Exp. Biol. Med.* 150(2): 513-516; 1975.

The possible existence of nicotinic or adrenergic receptors affecting pancreatic amylase release was investigated *in vitro* in pancreas tissue from White Swiss mice, and the secretory response to commonly used cholinergic analogs was compared in the same preparations. Acetylcholine, carbamylcholine, and methylcholine (acetyl-ß-methylcholine) all induced amylase release in a concentration-dependent manner, with a peak response between 3×10^{-7} M and 3×10^{-6} M; there was a much smaller response at higher concentrations. Bethanechol (carbamyl-ß-methylcholine) also induced amylase release, but at approximately 10-30 times the concentration for other agents. Nicotine (3×10^{-5} M), L-norepinephrine (10^{-4} M), and L-isoproterenol (10^{-4} M) had no effect on bethanechol (3×10^{-5} M)-stimulated or -unstimulated amylase release. The mean level of amylase release in response to 5×10^{-7} M acetylcholine (1.51 U/mg/30 min) was almost completely abolished by 3×10^{-6} M atropine (0.48 U amylase released/mg/30 min), while 10^{-4} M hexamethonium and 3×10^{-5} M D-tubocurarine were ineffective. The results confirm the muscarinic nature of the cholinergic receptor mediating amylase release, while no evidence to support a role for nicotinic or adrenergic receptors has been found. The previously reported ability of catecholamines to inhibit enzyme secretion *in vivo*, but not *in vitro* in these experiments, must be due to a change in pancreatic blood flow rather than to a direct effect on the pancreatic acinar cell.

5430 PANCREATIC SECRETION IN RESPONSE TO AN ELEMENTAL DIET AND INTRAVENOUS HYPERALIMENTATION. (Eng.) Kelly, G. A.; Nahrwold, D. L. (Coll. Medicine, Pennsylvania State Univ., Hershey, PA). *Surg. Gynecol. Obstet.* 143(1):87-91; 1976.

Because reports concerning the effects of elemental diets on pancreatic exocrine function have been conflicting, pancreatic responses to the intraduodenal administration of an elemental diet (Vivonex) were compared with responses to p.o. administration of the same mixture in dogs. The pancreatic responses to the elemental diet were compared with the responses to an i.v.-administered amino acid synthetic hyperalimentation solution. The mean volume of pancreatic juice stimulated by intraduodenal infusion in Vivonex (2.0 ml/15 min, 90 min) was not significantly different from that produced by the infusion of saline (1.9 ml/15 min). When the dogs were fed 90 ml of the mixture, however, the mean volume of pancreatic flow increased significantly ($p<0.05$) from a control (saline) level of 1.9 ml/15 min to 7.1 ml/15 min. When the diet was infused intraduodenally, the protein concentration was significantly increased (110 mg/ml), as was the total protein output (213 mg/15 min), over control values (82 mg/ml and 153 mg/15 min, resp.). Because of the relatively greater production of free water, a significant decrease in protein concentration (47 mg/ml) occurred when the diet was given p.o., but the total protein output (242 mg/ml) was increased. Both intraduodenal and p.o. administration caused significant increases in the bicarbonate concentration (25 and 60 µEq/ml, resp.) and bicarbonate output (49 and 461 µEq/15 min, resp.) in comparison with controls (14 µEq/ml and 29 µEq/15 min). The i.v.-administered hyperalimentation solution (1 or 2 ml/kg/hr) produced small but significant increase in the mean volume of pancreatic juice (2.4 ml/15 min), in comparison to controls (1.8 ml/15 min). There were small increases in mean protein concentration, protein output, bicarbonate concentration, and bicarbonate output at both rates of infusion. The results suggest that of the methods currently available for providing adequate nutrition, i.v. hyperalimentation has the least effect on pancreatic exocrine function. Although it is not possible to avoid significant stimulation to pancreatic secretion with this elemental diet, intraduodenal administration prevents the large output of water and electrolytes seen with p.o. administration.

SECRETION AND METABOLISM

Hepatobiliary Tract

5440 CIRCADIAN RHYTHM OF BILE SECRETION IN THE RAT. (Eng.) Balabaud, C.; Noel, M.; Beraud, C.; Dangoumau, J. (Laboratoire de Pharmacologie, Universite de Bordeaux II, 3, place de la Victoire, F-33000 Bordeaux, France). *Experientia* 31(11):1299-1301; 1975.

Experiments were carried out to determine whether bile flow in the rat follows a diurnal rhythm. Thirty-three male Wistar rats were housed for 8 days before the study in a dark room. The room was lighted between 0800 and 2000 hr, and the rats were fed from 2000 to 2400 hr. The rats were randomized into three groups of 11 each: group I was studied at 0800 hr, group II at 1700 hr, and group III at 2400 hr. The mean basal bile flow at 1700 hr (7.68 µl/min/100 g) was significantly lower than that at 0800 hr (9.49 µl/min/100 g, $p<0.01$) or at 2400 hr (8.95 µl/min/100 g, $p<0.01$). The estimated bile acid independent flow (BAIF), i.e., the intercept of the regression line for bile flow versus bile acid excretion rate with the vertical axis, expressed in µl/min/100 g body weight in group II (5.84), was significantly lower than that in group I (7.25 µl/min/100 g, $p<0.05$) or in group III (7.52 µl/min/100 g, $p<0.05$). Expressed in µl/min/g liver, the estimated BAIF was not significantly different in the three groups. The 22% decrease in BAIF between 2400 hr and 1700 hr paralleled a 19% decrease in liver weight. It is concluded that bile flow in the rat follows a diurnal rhythm, with a decrease at the end of the light period, far from the feeding period. The decrease is due to a reduction of the BAIF. Parameters such as food, light, and time schedule must be carefully checked in experiments concerning bile flow.

5441 THE CONSEQUENCES OF LIPID PEROXIDATION IN ISOLATED HEPATOCYTES. (Eng.) Hogberg, J.; Moldeus, P.; Arborgh, B.; O'Brien, P. J.; Orrenius, S. (Dept. Forensic Medicine, Karolinska Institutet, Solnavagen 1, S-10401 Stockholm 60, Sweden). *Eur. J. Biochem.* 59(2):457-462; 1975.

The biochemical and morphological effects of lipid peroxidation initiated by the addition of either ADP-complexed Fe^{3-} (50 mM ADP + 1.87 mM $FeCl_3$) or cumene hydroperoxide (30 mM) to isolated rat hepatocytes were investigated. To test cell membrane permeability, pyruvate (0.67 mM), and NADH (0.1 mM) were added to the cell medium, and the absorbance at 340 nm was measured. The oxidation of NADH in the fresh cell suspension was 13% of that achieved after lysis of the cells with 0.25% sodium deoxycholate; a control incubation by shaking the cells for 20 min at 37 C increased the rate of NADH oxidation to about 33% of the deoxycholate-stimulated activity. The latency of lactate dehydrogenase was further decreased to 38, 49, and 67% by the addition of 19, 44, and 187 µM ADP-complexed Fe, resp., and to 44, 49, 69, and 100% by the addition of 75, 150, 300, and 750 μM cumene hydroperoxide, resp. Alprenolol metabolism, which is a cytochrome P-450-dependent reaction, was decreased from a control level of 11.1 nmol x 15 min^{-1} x (10^{6} cells)$^{-1}$ to 10.7, 9.0, 5.9, 8.7, 7.6, and 0.9 after 20 min of incubation with 47, 187, and 370 μM ADP-complexed Fe or 150, 300, or 750 μM cumene hydroperoxide, resp. The inactivation was related to the amount of malonaldehyde formed with both inducers. The cumene hydroperoxide-induced lipid peroxidation was associated with a decomposition of cytochrome P-450, as revealed by the carbon monoxide difference spectra. The iron-induced reaction did not cause any decrease in the level of cytochrome P-450, but lower levels of lipid peroxidation were involved. The inhibition of microsomal oxidative drug metabolism was correlated with the release and subsequent inactivation of NADPH-cytochrome c reductase, while cytochrome P-450 destruction occurred only in the presence of high concentrations of cumene hydroperoxide (150 μM), which were associated with extensive malonaldehyde formation. There were also marked ultrastructural alterations in the hepatocytes (at 600 μM cumene hydroperoxide), which were not apparent after incubation in the presence of iron (≤187 μM Fe^{3+}). The changes included irregularly shaped endoplasmic reticulum with distended cisternae and dilated Golgi apparatuses, extracted cell sap, and disrupted plasma membranes. It is concluded that the isolated liver cell system provides a valuable tool for the study of lipid peroxidation and its pathological implications.

5442 AZO DYES AND HEPATIC VITAMIN A RESERVES.

(Fre.) Truhaut, R. (Centre de Recherches Toxicologiques, Universite Rene Descartes, 4, Avenue de l'Observatoire, F-75006 Paris, France). *Arzneim. Forsch.* 25(10):1594-1596; 1975.

To test the effects of Amaranth and Sunset Yellow FCF on vitamin A stored in the rat liver, 105 female Wistar rats, born of mothers fed 800 IU vitamin A per kg of food, were fed a vitamin A-deficient diet. Twelve animals were sacrificed after 10 days. Twelve animals received 30 g vitamin A per day for 10 days. The remaining animals were divided into 9 groups and received either 1,200, 3,000, 10,000, or 20,000 mg Amaranth or Sunset Yellow FCF per kg of food, in addition to 30 g per day of vitamin A for 10 days. Neither azo dye at any concentration had an effect on the growth, food consumption index, or percentage of vitamin A stored in the liver of young rats.

5443 EXPERIMENTAL STUDIES OF THE BILIARY ELIMINATION OF CONJUGATED BSP BY THE LIVER, IN VIVO, AND IN THE ISOLATED AND PERFUSED LIVER.

(Fre.) Catau, G.; Catau, R.; Besson, S.; Galipienso, A. M. (Faculte des Sciences pharmaceutiques et Biologiques, 7, rue Albert Lebrun, 54001 Nancy, France). *C.R. Soc. Biol. (Paris)* 169(3):637-640; 1975.

The biliary excretion of conjugated BSP by the liver *in vivo* and by isolated and perfused liver was studied to determine if the technique of perfusion affected the liver's capacity to metabolize BSP. The inhibitory effect of benziodarone on conjugation of BSP with glutathione was also studied. After injection of 15 mg/kg BSP, the percentage of BSP eliminated in the conjugated form was similar in the intact rat and in the isolated and perfused rat liver, (80-85% in the first hr and 90-95% for the last fractions eliminated). Carbon tetrachloride, 1 mg/kg, i.p., or amitriptyline, 50 or 100 mg, i.m., administered 24 hr before BSP injection, had no effect on level of conjugation. When the intact rat was pretreated with benziodarone, 50 mg/kg, i.p., either 1 hr before a single i.v. injection of BSP or before a continuous, slow perfusion of BSP, level of conjugation remained the same during the first hr the elimination of BSP was measured. However, during the second hr level of glutathione-injected BSP fell to 60-70% after a single injection of BSP and to 25% after end of perfusion of BSP. A similar decrease in level of conjugated BSP was observed when 100 μM of benziodarone was added to the perfusion fluid used in the *in vitro* studies of the isolated rat liver. Concentration of BSP in the perfusion fluid was 1 μM and of glutathione, 93 μM. It is hypothesized that benziodarone competes with BSP for glutathione or blocks the -SH group in cysteine, necessary for formation of the BSP-glutathione conjugate.

5444 COMPARATIVE STUDIES ON THE EFFECT OF CHOLESTEROL FEEDING ON BILIARY COMPOSITION.

(Eng.) Ho, K.-J. (Univ. Alabama Birmingham, Medical Center, Birmingham, AL 35294). *Am. J. Clin. Nutr.* 29(7):698-704; 1976.

The effect of cholesterol feeding (1.2 or 2% cholesterol by weight) on the biliary composition in six species (chickens, rabbits, rats, hamsters, ground squirrels, and prairie dogs) and their susceptibility to cholesterol cholelithiasis were investigated. The gallbladder or hepatic bile from all species had a uniformly low cholesterol content, far below its maximum solubility. The relative concentration of bile acid was higher in chickens and rabbits, and the relative concentration of phospholipid was higher in the other species. The cholesterol content remained constant in all six species (0.7-3%). Cholesterol feeding produced extreme hypercholesteremia in rabbits, ground squirrels, and prairie dogs, moderate hypercholesteremia in chickens and hamsters, and a slight elevation of serum cholesterol in rats. All animals developed cholesterol fatty liver. The gallbladder bile of prairie dogs reached the boundary of metastable supersaturation of cholesterol and subsequently developed cholesterol crystals and gallstones. A circadian change in the relative concentration of bile acid, cholesterol, and phospholipid in the hepatic bile of rats with chronic biliary drainage was observed as a consequence of cholesterol feeding. Cholesterol feeding selectively increased both the relative and absolute biliary cholesterol contents in hamsters and ground squirrels. The relative concentration of biliary cholesterol was increased in hens and roosters fed a cholesterol diet, but not in rats and rabbits. The reasons for species differences in response to cholesterol feeding and susceptibility to gallstone formation are not known. There may be some differences in the basic mechanisms involved in the biliary excretion of excessive hepatic cholesterol between species.

5445 THE EFFECT OF (+)-CATECHIN ON THE ALTERATIONS OF COENZYME A, CARNITINE AND THEIR FATTY ACID ESTERS INDUCED BY ACUTE ETHANOL APPLICATION IN THE RAT LIVER. (Eng.) Wolfert, W.; Goebell, H. *In: New Trends in the Therapy of Liver Diseases. Proceedings of the International Symposium on New Trends in the Therapy of Liver Diseases, Tirrenia, June 6-7, 1974.* (Basel: Karger):pp. 164-168; 1975.

The possible effects of (+)-catechin on the alterations in fatty acid metabolism that occur in acute ethanol intoxication were investigated in rats that received 35% ethanol (5 g/kg) by stomach tube. The mean amounts of free coenzyme A (CoA), acetyl-CoA, acyl-CoA, free carnitine, acetyl-carnitine, and acyl-carnitine (197, 51, 122, 66, 96, and 115 nmol/g fresh weight, resp.) were increased after ethanol administration, in comparison with controls receiving isocaloric glucose (107, 31, 60, 31, 42, and 77 nmol/g, resp.). (+)-Catechin (200 mg/kg), given intragastrically during ethanol administration and also 1 hr later, fully reversed the increased levels of free CoA, acetyl-CoA, acyl-CoA, free carnitine, and acyl-carnitine, the values being 98, 34, 60, 24, and 83 nmol/g, resp. Doubling the dose of (+)-catechin had no further effect on the levels of CoA or its derivatives, although it did normalize the level of acetyl-carnitine (51 nmol/g) and further decreased the level of acyl-carnitine (54 nmol/g). After ethanol administration, the hepatic acetoacetate content dropped significantly from a mean control value (controls received saline) of 83 nmol/g to 16 nmol/g; the level of β-hydroxybutyrate increased from a control level of 139 nmol/g to 310 nmol/g. (+)-Catechin (200 mg/kg) partly reversed the effect of ethanol, the difference being significant for acetoacetate (23 nmol/g, $p<0.05$), but not significant for β-hydroxybutyrate (255 nmol/g). The ratio of β-hydroxybutyrate to acetoacetate was 1.7 for controls, 19 for ethanol-treated rats, and 9 for ethanol-plus-(+)-catechin-treated rats. The mean concentration of free fatty acids was significantly increased in ethanol-treated rats (1,343 μval/l), in comparison with controls treated with glucose (734 μval/l), although (+)-catechin had no influence on this elevation. The results of this study correspond to those previously published.

5446 STABILIZATION OF RAT-LIVER LYSOSOMES BY (+)-CYANIDANOL-3 IN VIVO. (Eng.) Niebes, P.; Ponard, G. *In: New Trends in the Therapy of Liver Diseases. Proceedings of the International Symposium on New Trends in the Therapy of Liver Diseases, Tirrenia, June 6-7, 1974.* (Basel: Karger): pp. 128-139; 1975.

The *in vivo* effect of (+)-cyanidanol-3 on the lysosomal membrane was investigated in the livers of female Wistar rats. The discharge of three lysosomal enzymes, N-acetyl-β-glucosaminidase, β-glucuronidase, and acid phosphatase was measured in control rats and in animals on the following regimens: (+)-cyanidanol-3 (200 mg/kg/day, s.c.) for 12 days; D-galactosamine HCl (200 mg/kg/day, s.c.) for 7 days; D-galactosamine HCl for 7 days and (+)-cyanidanol-3 for 6 days; 10% ethanol for 4 weeks followed by 20% ethanol for 6 weeks; 10% ethanol for 4 weeks, 20% ethanol for 6 weeks, and (+)-cyanidanol-3 (100 mg/kg/day) for the last 20 days. D-galactosamine provoked a fragility in the lysosomes and increased the discharge of the enzymes by about 30%, while (+)-cyanidanol-3 reduced the fragility and diminished the discharge of enzymes by 15%. Ethanol provoked an abnormal fragility in the hepatic lysosomes, with an increased discharge of the three enzymes by 20%, compared to controls; (+)-cyanidanol-3 counteracted the effects. At a dose of 1 mg/ml, (+)-cyanidanol-3 had no effect on the discharge of enzymes or on their stability *in vitro*. The results show that (+)-cyanidanol-3 exercises a protective action on hepatic cells.

5447 EFFECT OF PHENOBARBITAL ON LIPID PEROXIDATION IN THE LIVER. (Eng.) Hahn, H. K. J.; Tuma, D. J.; Barak, A. J.; Sorrell, M. F. (Veterans Admin. Hosp., Omaha, NB 68105). *Biochem. Pharmacol.* 25(7):769-772; 1976.

Studies were carried out in male Sprague-Dawley rats to determine whether phenobarbital (PB) increases lipid peroxidation in the liver and to determine whether peroxidation is involved in the formation of fatty liver. The effect of *N,N'*-diphenyl-*p*-phenylenediamine (DPPD) on the inductive effects of PB was also studied. PB (50 mg/kg/12 hr, 5 days, i.p.) administration increased liver weight, NADPH cytochrome *c* reductase activity, and the content of cytochrome P-450. When DPPD (60 mg/100 g, i.p.) was given at intervals of 72 and 24 hr prior to PB and at 24 hr before sacrifice, the inductive effects of PB in the liver were not affected; there was, however, a decrease in body weight. PB caused a marked increase in diene conjugation when administered either with saline (0.449 optical density/mg phospholipid/ml) or with mineral oil (0.430 optical density/mg/ml), in comparison with controls that received saline (0.314 optical density/mg/ml) or mineral oil (0.295 optical density/mg/ml). DPPD did not alter the UV absorption of the microsomal lipids in controls, although it was effective in suppressing the increased lipid peroxidation resulting from PB treatment. The UV spectra for microsomal lipids and the different spectra between the mineral oil control and PB-treated animals showed that the increase in the diene conjugation peak of the microsomal lipids of the PB-treated rats ranged from 232 to 235 nm throughout the experiment. PB administration caused a three- to fivefold increase in hepatic triglyceride levels, compared to both the saline and mineral oil controls. DPPD administration resulted in a 60-70% inhibition of triglyceride accumulation in the rats that received PB. PB treatment caused a fivefold increase in malonic dialdehyde production (as measured by the thiobarbituric acid method) over controls (0.594 μg/mg protein versus 0.106 μg/mg protein). The results show that PB enhances hepatic lipid peroxidation and causes an accumulation of triglyceride in the liver; the latter confirms previous studies, which indicated that PB induces fatty liver in rats. The fact that DPPD was effective in preventing the increase in lipid peroxidation, as well as reducing the triglyceride accumulation resulting from PB treatment, suggests that the peroxidative process may play a role in the PB-induced fatty changes in the liver.

5448 MECHANISM OF ACTION OF PHENOBARBITAL ON BILIARY SECRETION.

(Fre.) Pavel, I.; Costiner, E.; Mitrache, L. (Institut d'Endocrinologie C. I. Parhon, Intrarea Caragiale nr. 6, Bucharest, Sect. II, 201, Rumania). *Ann. Gastroenterol. Hepatol.* 11(5):365-370; 1975.

The *in vitro* effects of phenobarbital on biliary secretion were studied in the rat. Isolated rat livers were perfused with 2 mg phenobarbital dissolved in 19 ml Ringer's solution. The perfusion lasted 2 hr. In controls (no phenobarbital) bile secretion occurred 25 min after the beginning of the perfusion, while in the treated animals, secretion began 2-3 min after the perfusion started. The volume of secretion increased by 34% and the concentration of bilirubin in the bile decreased by 41% in phenobarbital treated rats. It is hypothesized that the opening of the hepatic intercellular junctions (zonulae occludente) is responsible for the phenomenon.

5449 PROTECTIVE EFFECT OF SELENIUM ON CERTAIN HEPATOTOXIC AND PANCREOTOXIC MANIFESTATIONS OF SUBACUTE CADMIUM ADMINISTRATION.

(Eng.) Merali, Z.; Singhal, R. L. (Faculty Medicine, Univ. Ottawa, Ottawa, Ontario KIN 9A9, Canada). *J. Pharmacol. Exp. Ther.* 195(1):58-66; 1975.

The effects of subacute exposure to cadmium and selenium on hepatic carbohydrate metabolism and pancreatic function were assessed, and the protective effects of selenium on cadmium-induced biochemical and functional changes in male Sprague-Dawley rats were investigated. In subacute studies, rats were given either cadmium chloride (2 mg/kg/day, s.c.) or selenium dioxide (2 mg/kg/day, s.c.) in divided doses 12 hr apart for 7 days. The same doses were administered simultaneously in separate solutions in the protective studies. Cadmium alone significantly ($p<0.05$) elevated the levels of hepatic pyruvate carboxylase, phosphoenolpyruvate carboxykinase, fructose 1,6-diphosphatase, and glucose 6-phosphatase over controls, while selenium produced no significant change in enzyme levels. The simultaneous administration of cadmium and selenium significantly ($p<0.05$) lowered the activities of the glucogenic enzymes over those with cadmium alone. Similarly, cadmium caused a marked increase in the concentration of endogenous cyclic AMP ($p<0.05$), but selenium's values remained within the range of controls. The combined dose produced an elevation in cyclic AMP, which was similar to that for cadmium alone ($p<0.05$). Selenium pretreatment failed to significantly alter the resting blood glucose level or the normal response to a glucose load (2.0 g/kg, i.p.). Rats pretreated with cadmium displayed hyperglycemia and reduced glucose tolerance. The simultaneous administration of cadmium and selenium also caused a rise in resting blood glucose, but the increase was lower than that for cadmium alone. Prior to glucose administration, the serum immunoreactive insulin (IRI) concentration in selenium-treated rats remained within normal values, while that in cadmium-treated rats was markedly depressed. The glucose load produced a normal rise in the serum IRI level in selenium-treated rats, but a statistically significant depression was seen in rats given cadmium. In animals receiving both compounds, the glucose load produced greater increases in serum IRI concentrations than in those given cadmium alone. Cadmium pretreatment resulted in markedly reduced insulinogenic indices, suggesting that cadmium produces a decrease in pancreatic secretory activity. Selenium administration concurrent with that of cadmium appears to mitigate, in varying degrees, several cadmium-induced metabolic and functional changes.

5450 INFLUENCE OF A LONG OR MEDIUM CHAIN TRIGLYCERIDE DIET ON INTERMEDIARY HEPATIC METABOLISM OF THE RAT.

(Eng.) Bach, A.; Phan, T.; Metais, P. (Laboratoire de la Clinique medicale A, Hopital Civil, F-67000, Strasbourg, France). *Nutr. Metab.* 19(1/2):103-110; 1975.

To study the influence of the metabolism of medium chain triglycerides (MCT) on some aspects of the intermediary metabolism of the liver, two groups of male Wistar rats received, *ad libitum*, diets containing either MCT or long chain triglycerides (LCT), constituting 20% of the diet, for 4-5 weeks. The results were compared with those of a third group of rats fed a low-fat control diet, which contained 2.5% LCT. No difference in weight increase was found between the rats on the LCT and MCT diets. Total lipids and cholesterol concentrations in the plasma were also the same with both diets. The two high-fat diets caused an increase in the mean levels of hepatic acetyl coenzyme A (control, 27 nmol/g liver; LCT, 119 nmol/g; MCT, 111 nmol/g), citrate (control, 175 nmol/g; LCT, 341 nmol/g; MCT, 317 nmol/g), malate (control, 376 nmol/g; LCT, 580 nmol/g; MCT, 971 nmol/g), acetoacetate (control, 55 nmol/g; LCT, 101 nmol/g; MCT, 111 nmol/g, and β-hydroxybutyrate plus acetoacetate (control, 218 nmol/g; LCT, 277 nmol/g; MCT, 303 nmol/g). The concentration of acetoacetate plus β-hydroxybutyrate decreased in the blood from a control level of 182 nmol/ml to 134 nmol/ml in the animals fed LCT and to 111 nmol/ml in those fed MCT. No ketonuria occurred. In the rats fed MCT, the mean hepatic levels of ATP, AMP, and inorganic phosphate (3462, 1840, and 3791 nmol/g, resp.) were higher than those in the rats fed LCT (3133, 1453, and 2912 nmol/g, resp.). The levels of these substances were increased in both groups compared with the controls (2432, 680, and 893 nmol/g, resp.). The blood lactate and pyruvate concentrations in the LCT rats (458 and 22 nmol/ml, resp.) were significantly lower than those in controls (887 nmol/ml and 72 nmol/ml, resp.). Hepatic and blood lactate concentrations in MCT rats were at least equal to or slightly higher (not significantly) than those of controls. Hepatic glucose and glycogen and blood glucose concentrations were higher in rats fed the high fat diets. Replacing a low-fat diet with a high-fat one causes modifications of intermediary metabolism in the blood and liver, but there are fewer differences between LCT and MCT diets than might be expected.

5451 EFFECT OF PORTACAVAL ANASTOMOSIS ON THE ACTIVITIES OF HEPATIC ENZYMES RELATED TO CHOLESTEROL AND BILE ACID METABOLISM IN RATS.

(Eng.) Balasubramaniam, S.; Press, C. M.; Mitropoulos, K. A.; Magide, A. A.; Myant, N. B. (Medical Res. Council Lipid Metabolism Unit, Hammersmith Hosp., London, W12 OHS, United Kingdom). *Biochim. Biophys. Acta* 441(2):308-315; 1976.

The effect of portacaval anastomosis (PCA) on the activities of hepatic enzyme systems related to cholesterol metabolism was studied in inbred male Wistar rats. The rats were either given PCA and fed ad libitum, sham operated and pair-fed with the first group, or sham operated and fed ad libitum. Subcellular fractions from the livers were analyzed for enzyme activities, and content of bile acids, cholesterol, and protein. Total body weight, the liver weight, and the liver/body weight ratio were all significantly lower in the PCA-treated rats (208 ± 8 g, 3.8 ± 0.6 g, and 0.019 ± .004, resp.) than in the controls fed ad libitum (303 ± 11 g, 10.3 ± 0.3 g, and 0.034 ± 0.001, resp.). The total body weight of the PCA-treated rats was not significantly different from that of pair-fed controls, but their liver weight was half that of pair-fed controls. Cannulation of the bile duct reduced the body weight of both PCA and control rats fed ad libitum, but did not affect the liver/body weight ratio in either group. Total liver cholesterol was significantly lower in the PCA-treated rats and pair-fed controls (1.66 ± 0.1 mg/g and 1.20 ± 0.1 mg/g, resp.), than in controls fed ad libitum (1.98 ± 0.1 mg/g), but the liver microsomal concentration was significantly higher in the PCA-treated rats (44.9 ± 2.9) than in controls fed ad libitum (39.7 ± 4.1 mmol/mg protein). In the three groups of rats, the activities of hydroxymethylglutaryl-CoA reductase, cholesterol-7-alpha-hydroxylase, and tyrosine transaminase exhibited diurnal rhythm, each activity exhibiting between 1300 and 0100 hr. All three activities were significantly higher in the PCA-treated rats than in either set of controls at both times. Ethylmorphine demethylase activity was significantly lower in the PCA-treated rats than in controls. The amount of cytochrome P-450 per mg of microsomal protein was significantly lower in the PCA rats than in the pair-fed controls. In a separate group of 20 rats, PCA was administered to 10, and 10 were sham operated. The bile duct was cannulated in five rats from each group, the other five being sham operated for cannulation. Bile was collected for 48 hr, and the livers were assayed. In the controls fed ad libitum, the activity of cholesterol-7-alpha-hydroxylase was higher in cannulated rats (44.0 ± 3.9 pmol/min/mg protein) than in those with normal enterohepatic circulation (29.4 ± 3.2 pmol/min/mg protein). In PCA-treated rats, the enzyme activity was the same in cannulated (45.5 ± 3.9 pmol/min/mg protein) and noncannulated rats (43.5 ± 2.1 pmol/min/mg protein), and higher than in control rats with normal enterohepatic circulation (29.4 ± 3.2 pmol/min/mg protein). The bile acid pools per 100 g body weight were similar in the PCA and control rats. One day after cannulation, bile acid excretion assumed a diurnal rhythm in PCA and control rats, with a maximum in the dark period. Total bile acids secreted during the second 24 hr was significantly lower in PCA-treated rats than in controls fed ad libitum, but liver weight accounted for the difference. The results suggest that PCA-treated rat livers compensate partially for loss of mass by an increased capacity for cholesterol synthesis per unit mass, and that the effects of bile fistula and PCA on cholesterol-7-alpha-hydroxylase activity are mediated through a common mechanism or that the enzyme is fully depressed by PCA.

5452 SERUM GLYCOPROTEIN SYNTHESIS AFTER PARTIAL HEPATECTOMY IN THE RAT.

(Eng.) Serafini-Cessi, F. (Istituto di Patologia Generale, Via S. Giacomo 14, 40126 Bologna, Italy). *Biochem. J.* 158(1):153-155; 1976.

Experiments were designed to measure the *in vivo* incorporation of ^{14}C-glucosamine into serum proteins at various times after partial hepatectomy in Wistar rats. The specific radioactivity of amino sugars in serum proteins was compared with that of hexosamines bound to liver microsomal fractions. A rapid method of measuring the specific radioactivity of D-[1-^{14}C]-glucosamine is described; the method is based on the separation of a volatile chromogen. The rats received a single injection of D-[1-^{14}C]-glucosamine (10 μCi, i.p.). A decrease in the incorporation of ^{14}C-glucosamine into glycoproteins appeared in the regenerating livers. The maximum increase occurred 24 hr after the operation. The specific radioactivity of hexosamines was 133-692 counts/min/μmol between 0.75 and 24 hr after injection in the test animals and 277-1466 counts/min/μmol in sham-operated animals. After 72 hr, the rates of incorporation were similar in the two groups of animals. In regenerating livers 24 hr after operation, the specific radioactivity of hexosamines bound to liver microsomal fractions was halved in comparison with the sham-operated animals. The values of glucosamine incorporation in partially hepatectomized rats increased from hepatectomy, and after 72 hr, the specific radioactivity reached the same value as in the sham-operated animals. These results demonstrate that a day after partial hepatectomy, the synthesis of glycoproteins that are mainly extruded into the bloodstream is significantly decreased.

5473 INTESTINAL MUCOSAL CYCLIC GMP: REGULATION AND RELATION TO ION TRANSPORT. (Eng.) Brasitus, T. A.; Field, M.; Kimberg, D. V. (United States Air Force Maxwell Regional Hosp., Maxwell Air Force Base, AL 36112). *Am. J. Physiol.* 231(1): 275-282; 1976.

Because of the known stimulatory effect of α-adrenergic agonists on cyclic GMP (cGMP) levels in other tissues, the possible role of cGMP in the action of epinephrine on intestinal ion transport was studied in rabbits. Stimulation of α-adrenergic and muscarinic cholinergic receptors with carbachol (50 nmol/ml) in rabbit ileal mucosa *in vitro* produced 5- to 15-fold increases in cGMP concentrations that were maximal within 2 min and gone within 30 min. Cholecystokinin octapeptide (1 μM) and insulin (50 μM) caused similar increases in cGMP. None of these agents affected cAMP. The epinephrine-induced increase in cGMP was blocked by atropine at 100 μM, but not at 1 μM. Epinephrine stimulates active NaCl absorption and decreases short-circuit current (SCC) *in vitro*, the latter effect due to inhibition of HCO_3 secretion. Atropine (100 μM) blocked the NaCl absorption but not the decrease in SCC. *In vitro* additions of several concentrations of cGMP and 8-bromo-cGMP did not decrease SCC or alter Na fluxes. Thus, changes in the cGMP concentration have been directly correlated with changes in the active absorption of NaCl, but a causal relationship has not been proven.

5474 EFFECT OF DIET ON THE CIRCADIAN RHYTHM IN THE DIGESTIVE ENZYMES OF RAT SMALL INTESTINE. (Eng.) Saito, M.; Murakami, E.; Suda, M. (Sch. Medicine, Ehime Univ., Shigenobu, Ehime 791-02, Japan). *J. Nutr. Sci. Vitaminol. (Tokyo)* 22(1);63-65; 1976.

The circadian rhythm observed in the activities of many digestive enzymes may be closely related to the rhythm of food intake and not to the light-dark cycle. The circadian rhythm of the maltase and leucine aminopeptidase activities of the small intestine was examined in male Wistar rats that had been fed either a carbohydrate-free or protein-free diet. The rats were kept under a controlled lighting regime with a dark period from 1800 to 0600 hr. The animals were fed either the carbohydrate-free or protein-free diet from 0900 hr to 1500 hr for 2 weeks. The activities of maltase and leucine aminopeptidase were low during the night and high in the daytime, irrespective of the diet. The leucine aminopeptidase activity was significantly lower in rats fed a protein-free diet than those on a carbohydrate-free diet (i.e., high-protein diet) at all times of the day. Even when the rats were fed a protein-free diet, the leucine aminopeptidase activity showed clear circadian variation, with a similar pattern to that of rats fed a high protein diet. The maltase activity was lower in rats fed a carbohydrate-free diet than those on a protein-free diet at all times of the day, and a clear circadian rhythm was also observed in rats fed a carbohydrate-free diet. These results suggest that the control mechanism of the rhythms of the digestive enzymes in the small intestine is different from that of dietary induction of the same enzymes.

5475 SMALL-BOWEL RESECTION: ORAL INTAKE IS THE STIMULUS FOR HYPERPLASIA. (Eng.) Levine, G. M.; Deren, J. J.; Yezdimir, E. (111H3 Veterans Admin. Hosp., University and Woodland Avenues, Philadelphia, PA 19104). *Am. J. Dig. Dis.* 21(7):542-546; 1976.

To determine whether p.o. intake is a necessary prerequisite for small intestinal hyperplasia to occur in the residual gut after small bowel resection, the responses in rats that had undergone a 70-cm proximal intestinal resection 1 week previously were compared with those of sham-operated animals. Gut weight (54.1-78.4 mg/cm), mucosal weight (44.4-64.5 mg/cm), protein content (4.60-7.63 mg/cm), and DNA content (0.400-0.474 mg/cm) in each intestinal segment studied were significantly greater in the experimental animals fed a p.o. elemental diet (30% dextrose, 5% amino acids, electrolytes, and vitamins) than in sham-operated animals fed the same diet (34.7-51.8, 25.0-41.7, 2.20-3.82, and 0.244-0.334 mg/cm, resp.), reflecting that significant small bowel hyperplasia occurred both proximal and distal to the anastomosis in the resected animals. In five resected animals fed an i.v. diet identical to that given p.o., the mucosal weight of two bowel segments was greater than in controls. The protein and DNA contents of these segments were not significantly different from controls, indicating the hyperplasia did not occur. There were no differences in gut weight, mucosal weight, mucosal protein, or DNA content between resected or sham-operated rats that received the i.v. alimentation. P.o. intake is a necessary stimulus for small intestinal hyperplasia after resection.

5476 PATHOGENESIS OF SALMONELLA-MEDIATED INTESTINAL FLUID SECRETION: ACTIVATION OF ADENYLATE CYCLASE AND INHIBITION BY INDOMETHACIN. (Eng.) Giannella, R. A.; Gots, R. E.; Charney, A. N.; Greenough, W. B., III; Formal, S. B. (Veterans Admin. Hosp., Lexington, KY 40506). *Gastroenterology* 69(6):1238-1245; 1975.

The mechanisms of Salmonella-mediated ileal secretion, the activation of adenylate cyclase, and the inhibitory action of indomethacin were investigated in adult New Zealand albino rabbits (1.5-2.5 kg). Three ileal loops were constructed (20 cm in length): an experimental loop inoculated with 1.0 ml (10^9 organisms) *Salmonella typhimurium* or 0.1 cholera toxin, a control loop inoculated with sterile broth or boiled cholera toxin, and an uninoculated loop. After inoculation, the animals were sacrificed, and the mucosal homogenates were assayed for adenylate cyclase, cyclic AMP, adenosine 3',5'-monophosphate phosphodiesterase, Na^+-K^+-ATPase and Mg^{++}-ATPase activities, and protein concentration. The TML and SL 1027 strains of *S. typhimurium* were both studied. In some cases, animals were pretreated with indomethacin (30 mg/kg, s.c.) before inoculation with *S. typhimurium.* Infection with the TML strain of *S. typhimurium* produced an increase in mucosal adenylate cyclase activity (468 pmol cyclic AMP/mg protein/10 min) in comparison with controls (203 pmol cyclic AMP/mg/10 min), whereas infection with the SL 1027 strain did not. Cholera toxin produced a twofold increase in adenylate cyclase activity. Neither the bacterial strains nor the cholera toxin produced increases in Na^+-K^+-ATPase or Mg^{++}ATPase activity. Indomethacin pretreatment abolished both fluid secretion and adenylate cyclase activity produced by the TML *S. typhimurium* strain. In animals treated with cholera toxin, fluid secretion was 60% inhibited ($p<0.01$) by indomethacin; the adenylate cyclase level remained unchanged. Na^+-K^+-ATPase and Mg^{++}-ATPase activities were not affected by indomethacin. These results suggest that: *S. typhimurium* causes ileal secretion by stimulating adenylate cyclase, mucosal invasion alone (SL 1027) is not sufficient to activate adenylate cyclase, and Na^+-K^+-ATPase is not involved in salmonella-induced secretion. The mèchanism of salmonella activation of adenylate cyclase is unclear, but apparently differs from that of cholera toxin in that it is inhibited by indomethacin. This might be explained by the participation of prostaglandins in the salmonella activation process.

5477 ENZYMATIC ACTIVITY OF THE RAT SMALL INTESTINAL MUCOSA UNDER HEAT STRESS. (Rus.) Rachimov, K.; Demidova, A. I.; Korotina, N. A. (Inst. Physiology, Acad. Sci. Uzb. SSR, Tashkent, USSR). *Fiziol. Zh. SSSR* 62(4): 609-614; 1976.

GENERAL

5480 A SIMPLE METHOD FOR THE CULTIVATION OF RAT LIVER CELLS. (Eng.) Takaoka, T.; Yasumoto, S.; Katsuta, H. (Inst. Medical Science, Tokyo Univ., Shirokanedai, Minato-ku, Tokyo 108, Japan). *Jpn. J. Exp. Med.* 45(5):317-326; 1975.

A simple method for obtaining cultures of rat liver parenchymal cells using a newly developed proteolytic enzyme, Dispase I (a bacterial neutral proteinase), and a new synthetic enzyme, DM-153, is described. Preperfusion was unnecessary for the dissociation of liver cells (obtained from JAR-1 and JAR-2 rats) that were minced and digested in a medium consisting of 10% fetal calf serum and 90% DM-153, in which 1,000 U/ml Dispase had been dissolved. After shaking (37 C for 2-3 hr), filtration, and centrifugation (1,500 rpm for 10 min), the sedimented cells were suspended in a medium of the same composition. Aliquots of 10 ml were incubated at 37 C, and the medium was changed semiweekly. In subculturing, mechanical dispersion or digestion with trypsin (200 U/ml in phosphate-buffered saline) or Dispase I was used. Dispase I was dissolved in the previously described medium and used at room temperature. When the tissues were dissociated by Dispase treatment and cultured, most cells showed spherical shapes in 1 day of cultivation. By 10-14 days, epithelial sheets were sufficiently enlarged to be subcultured. At subculturing using Dispase I, epithelial cell sheets were not dissociated into single isolated cells, but formed small aggregates of epithelial cells. Cinemicrographic observation revealed that the epithelial cells exhibited little locomotion, but active cytoplasmic movement. Cell strains were successively established from liver tissues of embryo and suckling and adult rats. Culturing of cells in arginine-deficient medium indicated that the cultured liver cells were parenchymal cells. Biochemical analysis of two strains revealed that pyruvate kinase, glucose-6-phosphate dehydrogenase, hexokinase, glucokinase, and catalase activities were all present. In one strain in which chromosome analysis was carried out, there was a high frequency of diploid numbers in the karyotype, however, it was a pseudodiploid. Liver cells cultured in this way can be used for experiments in the early stage of serial cultivation.

5481 FUNCTIONAL T CELLS IN RABBITS GUT MUCOSAL LYMPHOCYTES.

(Eng.) Singal, D. P.; O'Neill, M.; Clancy, R.; Bienenstock, J. (Dept. Pathology Medicine, McMaster Univ., Hamilton, Ontario, Canada). *Gut* 17(5):325-327; 1976.

Functional studies of Peyer's patch and gut mucosa lymphocytes were performed in a mixed lymphocyte culture reaction (MLC), an *in vitro* measure of the capacity of thymus-derived cells (T cells) to recognize and respond to cell surface antigens. The studies were conducted in parallel with spleen and thymus lymphocytes from the same donor animals (New Zealand white rabbits) to compare the relative functional capabilities of mucosal lymphocytes. In one experiment, in which lymphoid T cells from one rabbit were responder cells, and mitomycin-treated spleen cells from another rabbit were stimulating cells in the MLC test, the stimulation ratio (SR, ratio of experimental counts/min) for thymus cells as responder cells was 20.49, for spleen cells 10.59, Peyer's patch cells 4.54, and for gut mucosal cells 4.81. In two other experiments, no differences were found in the SR values obtained with these lymphocytes as responder cells. When one-way MLC was performed with spleen cells from a rabbit as responding cells, and mitomycin-treated lymphoid T cells from another rabbit as stimulating cells, the SR with spleen cells as stimulating cells was 11.88, with thymus cells 11.38 and 5.59 (two experiments), with Peyer's patch cells 15.25 and 7.35, and with gut cells 13.73 and 8.03. The mitomycin-treated lymphocytes from Peyer's patch and gut mucosa produced as much proliferative response in allogenic spleen cells as did mitomycin-treated spleen or thymus lymphocytes, demonstrating the capability of these cells to stimulate in the MLC. SR obtained in a Peyer's patch X mitomycin-treated Peyer's patch combination was not different from that obtained for Peyer's patch X mitomycin-treated spleen combination; similar results were obtained for gut mucosa lymphocytes. It is concluded that functional T cells exist in rabbit gut lamina propria and Peyer's patches.

5482 THE ORIGIN OF IMMUNOGLOBULINS IN SALIVARY SECRETION OF SHEEP.

(Eng.) Cripps, A. W.; Lascelles, A. K. (Dept. Veterinary Medicine, Univ. Sydney, Sydney, N.S.W., Australia 2006). *AJEBAK* 54(2):191-195; 1976.

To examine the suggestion that in the external secretory organs of ruminants there is an inverse relationship between the capacity to selectively transfer immunoglobulin (Ig) IgG$_1$ and the development of the IgA secretory system, a comparative study was made on the secretion of IgG$_1$ and IgA into parotid and submaxillary saliva of sheep. The mean flow of submaxillary saliva (5.7 ml/hr) was considerably less than the flow of parotid saliva (40.6 ml/hr), but the output of immunoglobulins was at least five times greater from the submaxillary gland (IgG$_1$, 374.74 μg/hr; IgG$_2$, 59.39 μg/hr; IgA, 2,527.38 μg/hr, compared to 69.32, 13.41, and 74.21 μg/hr, resp., in parotid saliva). The concentration of IgA in the submaxillary gland (505.76 μg/ml) was also extremely high in comparison with the parotid gland (1.19 μg/ml). The relative predominance of the IgA system in the submaxillary gland was made clearer by comparing the IgA:IgG concentration ratios for the two secretions; the mean value for submaxillary saliva was 8.36 compared with a value of only 0.88 for parotid saliva. By expressing the specific activity of IgG$_1$ or IgG$_2$ in saliva as a percentage of the specific activity of the corresponding immunoglobulin in the plasma, it was found that all the IgG$_1$ and IgG$_2$ in saliva was derived from plasma, except IgG$_1$ in the submaxillary saliva of which 15.77% was derived locally. The results suggest that there is no relationship between the selective transfer of IgG$_1$ and the secretion of IgA into the saliva of sheep.

5483 SELECTIVE ENTRY OF IMMUNOBLASTS INTO GUT FROM INTESTINAL LYMPH.

(Eng.) Hopkins, J.; Hall, J. G. (Chester Beatty Res. Inst., Clifton Ave., Downs Rd., Sutton, Surrey SM2 5PX, U.K.). *Nature* 259(5541):308-309; 1976.

The ability of immunoblasts that enter the lymph from somatic nodes to home to the gut was compared with that of immunoblasts from intestinal lymph. The intestinal lymph duct and an efferent duct of one of the peripheral, somatic lymph nodes (popliteal, prefemoral, or prescapular) were cannulated in yearling sheep. Killed bacteria were injected s.c. into the drainage area of the cannulated somatic nodes; 4 days later, 20-40% of the cells in the efferent lymph consisted of immunoblasts. An 8-hr collection of either intestinal or efferent lymph was then incubated with ^{125}I-iododeoxyuridine. The labeled cells were returned to the animals, i.v., and the radioactivity present in the tissues was determined 20 hr later. Immunoblasts originating in the somatic nodes did not enter the small gut, but tended to localize in the spleen; in four experiments, only 0.4-0.9% of the injected radioactivity was present in the small intestine, while 16.0-21.0% of the radioactivity was present in the spleen. Conversely, the percentage of immunoblasts generated in intestinal lymph in the small intestine was 27.0-35.3% in seven experiments, while the percentage of these immunoblasts found in the spleen was only 0.2-1.4%. Immunodiffusion revealed that detergent extracts of washed cells from intestinal lymph always contained immunoglobulin A (IgA) as the major immunoglobulin; extracts of lymph cells from stimulated somatic nodes contained mainly IgG, but no IgA. Furthermore, the immunoblasts from somatic nodes did not acquire the ability to home to the gut even when they were incubated in IgA-rich isologous intestinal lymph plasma. Therefore, one of the intrinsic cellular factors that mediates the extravasation of immunoblasts in the small gut must be the production of IgA or a closely-associated molecule.

5484 FACTORS WHICH DETERMINE THE ACCUMULATION OF IMMUNOBLASTS IN GUT AND SKIN. (Eng.)

Parrott, D. M. V.; Rose, M. L.; de Freitas, A.; Bruce, R. G.; Sless, F. (Western Infirmary, Glasgow G11 6NT, Scotland). *Agents Actions* 6(1/3):32-39; 1976.

The capacity of immunoblasts from two sources (peripheral lymph nodes draining the site of application of a contact sensitizer and mesenteric lymph nodes from mice infected with the gut parasite, *Trichinella spiralis*) to migrate to the gut and to inflamed skin sites was compared. The cells were labeled with ^{125}I-iododeoxyuridine and transferred to syngeneic recipients. The peripheral lymph node blasts readily entered skin sites in a nonspecific way, but failed to migrate to the gut, even when inflammation was induced. By contrast, the mesenteric lymph node blasts readily migrated to the gut in normal mice and in increased amounts to the gut of mice infected with *T. spiralis* or inflamed with p.o. turpentine. A small proportion of mesenteric lymph node blasts did, however, migrate, nonspecifically to the skin, but in much smaller amounts than peripheral lymph node blasts. It is concluded that the migration of immunoblasts to the gut has some specificity related to the source from which the cells were taken, but little specificity with regard to intraluminal antigen.

5485 THE DEFINITIVE VALUE OF ACTIVE-SPECIFIC IMMUNOTHERAPY FOR EXPERIMENTAL CARCINOMA OF THE COLON. (Eng.)

Enker, W. E.; Jacobitz, J. L. (Univ. Chicago Hosp., Dept. Surgery, 950 E. 59th St., P.O. Box 441, Chicago, IL 60637). *Surgery* 80(2):164-170; 1976.

The value of active-specific therapy for colon cancer was studied in syngeneic Wistar/Furth rats with WFCC-3 adenocarcinoma of the colon, induced by 1,2-dimethylhydrazine-diHCl. Adult, age-matched rats were inoculated i.p. with 2 x 10^5 viable tumor cells on day zero. All tumor cells had received 5,000 rads of x-irradiation before injection. Rats were immunized s.c. eight times through the first 21 days after tumor inoculation, and then weekly until day 35. The experiments were ended at day 180. The rats were divided into five treatment groups, which were immunized, resp., with concanavalin A (Con A)-modified tumor cells, vibrio cholerae neuraminidase (VCN)-modified tumor cells, cells modified with both agents, unmodified cells, and a tissue culture medium. Immunotherapy with both modified and unmodified cells resulted in a better absolute survival rate than did sham treatment. At 113 days after tumor inoculation, 80% of the sham-treated animals were dead, while 50% of these animals immunized with unmodified tumor cells were alive with no evidence of ascites. The survival of animals treated with Con A-modified cells was 60% and that of animals treated with VCN or both agents was 70%. Immunotherapy with VCN or both agents resulted in a statistically better survival rate than did sham therapy ($p<0.05$). There was no significant difference in survival between tumor cell and modified tumor cell therapy nor between tumor cell and sham therapy. At 180 days after tumor implantation there were no remaining rats with detectable ascites or other evidence of illness. The results indicate that active-specific immunotherapy with VCN or Con A-modified syngeneic tumor cells for experimental colon and rectal cancer may be an effective form of inhibiting tumor growth and achieving cure, and is a promising form of postoperative adjuvant therapy for human colon cancer.

5486 PATHOPHYSIOLOGY OF AGANGLIONIC COLON SEGMENT: AN EXPERIMENTAL STUDY ON AGANGLIONOSIS PRODUCED BY A NEW METHOD IN THE RAT. (Eng.)

Imamura, K.; Yamamoto, M.; Sato, A.; Kashiki, Y.; Kunieda, T. (Gifu Univ. Sch. Medicine, Tsukasa-machi, Gifu, Japan). *J. Pediatr. Surg.* 10(6):865-873; 1975.

The pathophysiology of an experimentally produced aganglionic colon segment in albino Wistar rats was evaluated to determine the mechanisms by which the defect of the intramural nerve plexi in Hirschsprung's disease induces narrowing of the intestinal segment and by which it causes the disappearance of peristalsis. Aganglionosis was induced in a colonic segment proximal to the peritoneal reflection by intraluminal filling with 0.01% corrosive sublimate in normal saline solution maintained at 50 mm Hg for 1 hr. When the length of the aganglionic segment was more than 3 cm, ileus appeared and megacolon proximal to a narrow segment was observed. Histologically and histochemically, total denervation was observed in the aganglionic segment; this is in contrast to findings in narrow segments of Hirschsprung's disease, in which intramural extraneous nerves are increased. When aganglionic colonic segments were observed under physiologic pressure, neither the high amplitude rhythmic contraction waves nor a reaction to stretch stimulation was observed. When 5 x 10^{-5} g/ml of barium chloride was applied to the same colonic segments, high amplitude rhythmic waves appeared, but there was still no inhibitory reaction to stretch stimulation. There may be contributing factors other than aganglionosis in the etiology of Hirschsprung's disease of the ultrashort segment, if this entity of the disease really exists. Aperistalsis observed in experimental aganglionic segments and that observed in aganglionic segments of Hirschsprung's disease seems to be based on the absence of the nonadrenergic, noncholinergic nerves.

5487 NEURAL CONTROL OF BLOOD FLOW IN GASTRIC MUCOSA. (Eng.) Kalahanis, N. G.; Das Gupta, T. K.; Nyhus, L. M. (Univ. Illinois Medical Center, 840 South Wood St., Chicago, IL 60612). *Am. J. Surg.* 131(1):86-90; 1976.

The mode of innervation of the small blood vessels in the fundic mucosa of male Sprague-Dawley rats was studied ultrastructurally, and the effects of vagotomy on this innervation were investigated. In control animals, individual axons either in the form of nerve endings or axonal varicosities devoid of Schwann cell sheaths were frequently seen in intimate contact with the vascular wall. In tissue examined from 24 hr to 7 days after vagotomy, a number of axonal profiles showed signs of degeneration, i.e., empty spaces in the axoplasm, vacuolation, myelin figures in the mitochondria, and clumping of empty vesicles. Only a relatively small proportion of nerve endings had undergone degeneration, even after 7 days. Nerve endings innervating the arterioles were also found to be degenerated. The morphology of capillaries was different from that in the controls. In cross sections, the capillary endothelium was thinner, there were fewer endothelial cell projections inside the lumen, and the capillary fenestrae seemed to be wider. These findings provide morphologic evidence for the neural control of blood flow in the rodent gastric mucosa.

5488 PRIMATE GASTRIC CIRCULATION: EFFECTS OF CATECHOLAMINES AND ADRENERGIC BLOCKADE. (Eng.) Zinner, M. J.; Kerr, J. C.; Reynolds, D. G. (Walter Reed Army Inst. Res., Washington, DC 20012). *Am. J. Physiol.* 230(2):346-350; 1976.

The effects of intra-arterial injections and infusions of epinephrine, norepinephrine, and isoproterenol on gastric blood flow were studied in 10 anesthetized baboons. Blood flow was measured electromagnetically before and after alpha-adrenergic blockade with phenoxybenzamine hydrochloride (1.5 mg/kg) or beta-adrenergic blockade with propranolol (0.5 mg/kg, i.v.). Using saline as a diluent, the catecholamines were injected intra-arterially as a 0.1-ml bolus in doses ranging logarithmically from 10^{-3} to 10^{0} μg (base)kg. At 10^{-3} μg/kg, epinephrine elicited a decrease in blood flow of 0.35 ± 0.12 ml/min/kg; as the dose was increased, the constrictor response increased to 2.90 ± 0.36 ml/min/kg at the highest dose. Alpha-adrenergic blockade significantly reduced this vasoconstrictor response ($p<0.001$), although beta-adrenergic blockade had no effect. Intra-arterial injection of norepinephrine over the same dose range resulted in a similar response; at the highest dose, the decrease in flow was 2.42 ± 0.39 ml/min/kg, and alpha-adrenergic blockade significantly attenuated the response ($p<0.01$). The injection of isoproterenol resulted in a linearly dependent increase in blood flow with increasing doses; at the highest dose, blood flow increased 2.06 ± 0.39 ml/min/kg. Only beta-adrenergic blockade affected the responses ($p<0.001$). When epinephrine and norepinephrine were infused (0.05 μg [base]/kg/min, 10 min), sustained vasoconstriction was seen, with no evidence of autoregulatory escape and no postinfusion "overshoot." At 3 min of infusion of epinephrine and norepinephrine, the blood flow had decreased to 1.27 ± 0.32 ml/min/kg and 2.18 ± 0.28 ml/min/kg, resp. There was a sustained increase in flow during the infusion of the same dose of isoproterenol, which was significantly attenuated by beta-adrenergic blockade. The results indicate a species difference in the adrenergic mechanisms of the gastric circulation between the dog and the subhuman primate. Epinephrine and norepinephrine might provide alternatives to vasopressin as a vasoconstrictor for the control of upper gastrointestinal bleeding.

5489 CHANGES IN INTESTINAL VASCULAR DIAMETER DURING NOREPINEPHRINE VASOCONSTRICTOR ESCAPE. (Eng.) Guth, P. H.; Ross, G.; Smith, E. (Veterans Admin. Wadsworth Hosp., Los Angeles, CA 90073). *Am. J. Physiol.* 230(6):1466-1468; 1976.

The hypothesis that escape from norepinephrine (NE)-induced vasoconstriction in the intestine is due to relaxation of initially constricted vessels was tested in 18 anesthetized cats. Intestinal blood flow was measured by an electromagnetic probe on the superior mesenteric artery. Intestinal submucosal and muscle arterioles and small mesenteric arteries were studied by *in vivo* microscopy with an image-splitting technique. Continuous recordings of mesenteric flow and vessel diameter were made during the infusion of NE (1-2 μg/min for 3 min) into the superior mesenteric artery. Mesenteric flow decreased soon after the NE infusion began, but then escaped. Microscopically, arterial constriction and escape were noted in submucosal, muscle, and mesenteric vessels, with a time course similar to that for flow. The mean escape index for flow for the 18 cats was 0.60 ± 0.05. The mean escape from constriction in the small mesenteric artery, muscle arteriole, and submucosal arteriole was 93.7, 106.9, and 92.6% of the control, resp. Arteriovenous anastomoses were not seen. These findings support the hypothesis that escape from NE-induced vasoconstriction is due to relaxation of initially constricted vessels.

5490 ABSENCE OF A CIRCADIAN RHYTHM IN CRYPT CELL MITOTIC RATE FOLLOWING CHEMICAL SYMPATHECTOMY IN RATS. (Eng.) Tutton, P. J. M. (Dept. Anatomy, Monash Univ., Clayton, Victoria, 3168, Australia). *Virchows Arch.* [*Cell Pathol.*] 19(2):151-156; 1975.

To evaluate the proposal that adrenergic neurons of the mucosal plexus are an important factor in regulating crypt cell proliferation, the circadian rhythm in food intake and in mitotic rate of jejunal crypt cells was examined in normal Sprague-Dawley rats that were chemically sympathectomized by 6-hydroxydopamine (100 mg/kg, i.v.). The rats were maintained in darkness from 21.00 to 07.00 hr. Both normal and sympathectomized animals showed a distinct circadian rhythm in food intake, with a peak during the interval 00.00 to 04.00 hr and a nadir around 08.00 to 12.00 hr. At no stage was there a statistically significant difference between the 4-hourly food consumption in control and sympathectomized animals. The mitotic rates in controls showed a distinct circadian rhythm, with a peak of 0.076 mitoses/cell/hr between 00.00 and 04.00 hr and a nadir of 0.029 mitoses/cell/hr between 06.00 and 10.00 hr. In contrast, only small variations were seen between mitotic rates at different times of the day; the mean mitotic rates were 0.037 at 00.00-04.00 hr, 0.041 at 06.00-10.00 hr, 0.032 at 12.00-16.00 hr, and 0.032 at 18.00-22.00 hr. The results show that in normal rats, the circadian rhythm in the crypt cell mitotic rate is closely correlated to that in food consumption, and that following chemical sympathectomy, the circadian rhythm in food consumption persists, but that in cell proliferation does not. The normal circadian rhythm in crypt cell proliferation may be mediated by variations in the rate of release of noradrenalin from the neurons of the mucosal plexus. Alternatively, normal secretion of noradrenalin by the neurons of the mucosal plexus may be a necessary cofactor for some other mechanism (e.g., a chalone), which controls the circadian rhythm in the crypt cell mitotic rate.

5491 CLEARANCE RATE, HALF-LIFE, AND SECRETORY POTENCY OF HUMAN GASTRIN-17-I IN DIFFERENT SPECIES.

(Eng.) Boniface, J.; Picone, D.; Schebalin, M.; Zfass, A. M.; Makhlouf, G. M. (Medical Coll. Virginia, Richmond, VA). *Gastroenterology* 71(2):291-294; 1976.

To test the hypothesis that a given dose of exogenous gastrin I should elicit higher serum concentrations in man compared with smaller animals, the clearance rates of synthetic human gastrin-17-I were measured in two human volunteers, four dogs, and four cats. The half-life of disappearance and acid secretory potency (D$_{50}$) were also measured in man and dog. The human subjects received four 60-min i.v. infusions of gastrin-17-I (5.4-343 pmol/kg/hr) and two prompt i.v. injections of gastrin (21 and 84 pmol/kg). The dogs received two 60-min infusions (164 and 328 pmol/kg/hr), and cats received an infusion of 328 pmol/kg/hr. The mean clearance rates in the dogs (2.9 l/kg/hr) and cats (8.1 l/kg/hr) were, resp., 3 and 8 times greater than in man (1.05 l/kg/hr). Accordingly, the mean half-life of gastrin-17-I in the dog (3.5 min) was 3 times shorter than in man (10.6 min). The mean D$_{50}$ in the human subjects was 42 pmol/kg/hr, while the mean D$_{50}$ in dogs was approximately 150 pmol/kg/hr. These exogenous doses, yielded approximately similar increments of serum gastrin in the two species, a clear indication that normal man and dog are equally sensitive to gastrin-17-I at a cellular level. In the cat, the D$_{50}$ was also dependent on the gastrin clearance rate. An inverse allometric relation between clearance rate and body weight was consistent with the known greater efficiency of metabolic and eliminatory processes in species of small size. Recent studies of the disposal of other gastrointestinal hormones indicate that the concepts developed theoretically for secretory stimulants, and confirmed experimentally for gastrin-17, may have wider applicability.

5492 EFFECTS OF 13-nle-MOTILIN ON SALIVARY, GASTRIC, AND PANCREATIC SECRETIONS IN MAN.

(Eng.) Domschke, S.; Domschke, W.; Schmack, B.; Tympner, F.; Junge, O.; Wunsch, E.; Jaeger, E.; Demling, L. (Dept. Medicine, Univ. Erlangen-Nuremberg, D-852 Erlangen, W. Germany). *Am. J. Dig. Dis.* 21(9):789-792; 1976.

Because previous studies have shown that natural and synthetic motilin enhances gastric pepsin output with no change in acid secretion in dogs and man, the potential effects of synthetic motilin, 13-norleucine-motilin (13-nle-motilin), on human salivary, gastric, and pancreatic secretions were studied. Healthy subjects received a continuous infusion of 13-nle-motilin (0.1 μg/kg/hr, i.v.). In six volunteers, pepsin secretion (2,616 ± 1,134 IU/hr) was significantly elevated over the mean basal level (1,714 ± 1,045 IU/hr, $p<0.05$) within 60 min of 13-nle-motilin infusion. Enhanced secretion was not associated with increased cyclic AMP output (mean basal level=257 ± 54 pmol/mg DNA; after motilin=262 ± 28 pmol/mg DNA). The gastric protein output and the basal acid output were unaltered by 13-nle-motilin; the latter result was in keeping with unchanged mean serum gastrin levels amounting to 69 ± 41 pg/ml before and 66 pg/ml after 13-nle-motilin administration. In the same six subjects, the infusion of 13-nle-motilin produced no significant changes from basal levels of bicarbonate, amylase, or protein contents of the saliva, or in its volume. In the five subjects tested, 13-nle-motilin did not significantly change the bicarbonate, amylase, trypsin, chymotrypsin, or lipase secretion of the pancreas from the basal levels. The bicarbonate output rose from a median basal level of 0.2 mEq/hr to 30.6 mEq/hr after secretin infusion (1 clinical U/kg/hr, i.v.), and the administration of 13-nle-motilin combined with secretin produced an identical value for the median bicarbonate output. Increases in pancreatic enzyme secretion after secretin alone or combined with 13-nle-motilin were not statistically significant. These studies show that the pepsigogic effect of 13-nle-motilin is not accompanied by any appreciable change in gastric H$^+$ secretion, which is compatible with the fact that serum gastrin levels remain unchanged by 13-nle-motilin. Cyclic AMP apparently does not serve a messenger role in 13-nle-motilin-stimulated pepsin secretion.

5493 SELECTIVE SYNTHESIS AND ACCUMULATION OF NUCLEAR NON-HISTONE PROTEINS DURING CARCINOGENESIS OF THE COLON INDUCED BY 1, 2-DIMETHYL-

HYDRAZINE. (Eng.) Boffa, L. C.; Vidali, G.; Allfrey, V. G. (The Rockefeller Univ., New York, NY 10021). *Cancer* 36(6):2356-2363; 1976.

The changes in the nuclear protein composition of colonic epithelial cells during 1,2-dimethylhydrazine (DMH)-induced carcinogenesis, particularly those in the nonhistone proteins, were studied in CFN (Wistar strain) male rats. Rats were given DMH (20 mg/kg, s.c.) and killed after 3, 7, 9, 11, 13, 15, 17, 19, and 21 weeks, 1 week after the last treatment. Nuclei were isolated from the colonic epithelium, the proteins were extracted, and the nonhistone proteins were analyzed by electrophoresis in polyacrylamide gels. Amino acid analyses were done on the prominent protein bands, and double-labeling experiments were performed to compare the rates of nuclear protein synthesis in treated and control rats. Electrophoresis of protein from tumors appearing during the 21st week of treatment showed a clear difference between the banding patterns of the tumor protein and of protein from control rats and normal epithelium surrounding the tumor. There were striking increases in proteins of molecular weights 44,000, and 62,000 that dominated the nonhistone protein profile in the tumor cell nuclei. There was a progressive increase in the nuclear concentration of these two proteins after increasing times of exposure to DMH. By the 21st week, nuclei had over three times the content of proteins with molecular weights of 44,000 and 62,000 more than in the third week. Using the 62,000 molecular weight protein as an index, the percentage of transformed cells ranged from 19 ± 4% at 7 weeks to 45 ± 8% at 19 weeks of treatment. ^{14}C-leucine incorporation into the nuclear protein of normal intestinal epithelium was compared with that of ^{3}H-leucine in rats treated with DMH for 4 weeks. The ratio of incorporation of the two labels was constant for most of the nuclear proteins, except for two divergent bands in the 40-45,000 and 60-65,000 molecular weight regions. When the labels given to treated and untreated rats were reversed, the ratio showed inversions in the same region of the gel. Amino acid analysis of the two bands showed both to be highly acidic, with a predominance of glutamic and aspartic acids over lysine, arginine, and histidine. Proline, cysteine, and methionine were lacking in both bands. The results indicate that carcinogenesis of the colon involves a selective accumulation within the nucleus of two protein classes, the syntheses of which are selectively accelerated very early after administration of the carcinogen.

5494 THE INFLUENCE OF HYPERCALCEMIA ON BASAL AND CHOLECYSTOKININ-STIMULATED PANCREATIC, GALLBLADDER, AND GASTRIC FUNCTIONS IN MAN.

(Eng.) Malagelada, J.-R.; Holtermuller, K. H.; Sizemore, G. W.; Go, V. L. W. (Mayo Clinic, Rochester, MN 55901). *Gastroenterology* 71(3):405-408; 1976.

Because clinical and experimental evidence indicates that hypercalcemia affects gastrointestinal function, the effects of hypercalcemia on basal and cholecystokinin (CCK)-stimulated pancreatic, biliary, and gastric outputs were investigated in 11 healthy subjects by a gastroduodenal perfusion technique. During normocalcemia, a submaximal CCK stimulus [0.016 Crick-Harper-Raper (CHR) U/kg/min, i.v.] increased trypsin output from a mean basal level of 2.6 kg/hr to 9.8 kg/hr, and maximal stimulation (0.25 CHR U/kg/min) produced a further increase (45.0 kg/hr). During hypercalcemia, which was induced by a 2-hr i.v. loading dose of 4 mg/kg/hr $CaCl_2$ followed by a maintenance dose of 1.75 mg/kg/hr, the mean basal rate of trypsin secretion (4.8 kg/hr) was higher than during normocalcemia. Submaximal stimulation with CCK produced an increase to 16.2 kg/hr. The difference between submaximal trypsin outputs with and without hypercalcemia was greater than the increment caused by hypercalcemia on basal enzyme output ($p<0.05$), suggesting that hypercalcemia potentiated CCK action on pancreatic enzyme secretion. In contrast, the trypsin response to maximal CCK stimulation (50.9 kg/hr) was not increased by hypercalcemia. Only the maximal CCK stimulus produced gallbladder contraction, resulting in a sharp peak of bilirubin output; this was magnified by hypercalcemia. The mean accumulated (3-hr) bilirubin output was significantly greater with hypercalcemia (116.7 mg) than without (69.3 mg, $p<0.01$), suggesting that hypercalcemia potentiates the stimulatory action of CCK on the gallbladder. During normocalcemia, the submaximal CCK stimulation significantly increased gastric acid output from a mean basal level of 1.2 mEq/hr to 2.5 mEq/hr; the maximal stimulation increased it to 3.4 mEq/hr. Hypercalcemia significantly increased the basal level to 2.9 mEq/hr, the submaximally stimulated level to 4.5 mEq/hr, and the maximally stimulated level to 4.8 mEq/hr. The serum gastrin levels were unaffected by CCK infusion, but hypercalcemia slightly but significantly increased the levels ($p<0.05$). These studies suggest that hypercalcemia in man affects pancreatic and gastric secretory functions and enhances the responsiveness of pancreas and gallbladder to hormonal stimulation with CCK.

5495 TOTAL DEVASCULARIZATION OF THE LIVER: AN EXPERIMENTAL MODEL OF ACUTE LIVER FAILURE.

(Eng.) Tonnesen, K. (Dept. Medicine A, Rigshospitalet, Copenhagen, Denmark). *Scand. J. Gastroenterol.* 11(Suppl. 37):23-26; 1976.

An experimental model of clinical liver failure, using total devascularization of the liver, was tested in six pigs. The mean survival time was 1,496 min. The immediate cause of death was cardiovascular collapse. The mean serum sodium concentration was significantly less postoperatively (134 mEq/l) than preoperatively (140 mEq/l), and the mean serum potassium concentration was significantly greater postoperatively (7.0 mEq/l) than preoperatively (4.1 mEq/l). The terminal drop in blood pressure was not responsible for these changes, since the blood pressure remained stable while the changes were statistically significant. The mean concentration of lactate in the cerebrospinal fluid was significantly increased in the experimental pigs just prior to death (5.72 mM) in comparison to that in normal pigs (1.65 mM). This was probably not due to cerebral anoxia, as the potassium concentration remained constant (3.2 mM in normal pigs; 3.8 mM in experimental pigs). The mean cerebrospinal fluid glucose concentration was significantly lower in the animals with liver insufficiency (2.69 mM) than in nonoperated animals (3.32 mM), and the cerebrospinal fluid to blood ratio was significantly decreased (from 0.79 to 0.43). This suggests that anaerobic glycolysis is responsible for the increased lactate concentration in the animals with liver insufficiency. The decreased cerebrospinal fluid glucose concentration may be caused by a decreased permeability through the blood brain barrier.

5496 A NEW METHOD TO STUDY THE HEALING DYNAMICS OF ACUTE GASTRIC EROSIONS AND ITS APPLICATION ON RESTRAINED RATS. (Eng.) Dutton, J. W.; Gwise, P. J.; Chiu, C. J.; Mersereau, W. A.; Hinchey, E. J. (Montreal General Hosp., Montreal, Quebec H3G 1A4, Canada). *J. Surg. Res.* 20(5):499-504; 1976.

Experiments were carried out in female Sprague-Dawley rats to establish a normal healing curve for acute gastric stress erosions and to determine if erosions occur at anatomically predetermined locations, subject to recurrent ulceration following repeated episodes of stress. Stress consisted of placing the rats in restraint cages in a darkened, cold room at 4 C for 3 hr. In rats killed immediately after being stressed (10 rats), typical acute erosions were grossly recognized by the presence of blood in the ulcer crater Ten groups of 10 rats each were subjected to stress and then injected i.v. with 0.2 mg of colloidal carbon (particle diameter 100-200 A); the surviving rats in each group were sacrificed at daily intervals from 1-10 days after stress. Biopsies of erosions taken every day following stress were grossly recognized by the presence of carbon particles. Almost all the acute erosions showed reestablishment of an intact, superficial epithelial layer by 24-48 hr. However, a crater remained, and the gastric glands beneath the intact epithelium were disorganized or incomplete. By day 5, more than 50% of the biopsied lesions were healed (defined as the return of a normal glandular pattern and the absence of a mucosal crater). By day 10, more than 90% of the biopsies were healed. Restressing of 20 rats 8 days following an initial stress resulted in the formation of acute gastric erosions similar to those seen following the initial insult. Biopsies of 21 carbon-labeled areas revealed that 19 erosions had healed during the 8-day period. None of the healed, carbon-labeled areas showed evidence of repeated mucosal damage as a result of the second episode of cold restraint, suggesting that there are no anatomically predetermined sites for the formation of acute stress erosions in this model.

5497 A METHOD OF CHOLECYSTOGRAPHY APPLICABLE TO SMALL LABORATORY ANIMALS. (Eng.) Poilly, J.-N.; Halls, J. M.; Buckley, G. C.; Currie, D. J. (St. Michael's Hosp., Univ. Toronto, Toronto, Ontario, Canada). *Gastroenterology* 71(2):228-231; 1976.

A method of i.p. cholecystography is described; it was tested in mice, guinea pigs, and rabbits with experimentally induced gallstones. Twenty-two female Swiss mice were given i.p. injections of 51.6% meglumine iodipamide (3 ml/kg) diluted 10-fold with water. Plain posterior-anterior radiographs of the abdomen were taken 2 hr later; the mice were then fed for 8 weeks on a lithogenic diet. Intraperitoneal cholecystography was repeated using the same dose of meglumine iodipamide; 3-4 days later, a repeat dose of 5 ml/kg was given in cases of nonvisualization of the gallbladder. Twenty mice on the normal diet gave a good gallbladder shadow with the first dose, and the other two gave a satisfactory cholecystogram when the dose was increased to 4 ml/kg. After 8 weeks on the lithogenic diet, cholecystography failed to visualize the gallbladder in 19 mice. All 19 were found to have small gallstones at laparotomy. Two of the three remaining mice had no stones. Intraperitoneal cholecystograms were performed in guinea pigs using doses of contrast medium up to 6 ml/kg diluted 5- to 10-fold, and in rabbits using 4 ml/kg diluted 2- to 3-fold. The gallbladders in both species were opacified, the guinea pig requiring at least 5 ml/kg of contrast medium. The reason for nonopacification of the gallbladders containing stones remains unclear, but previous studies have suggested that in acute cholecystitis, protein leaks into bile and brings about an inflammatory exudate that dilutes any radioopaque material within it.

5498 PORCINE PANCREATIC TRANSPLANTS. II. ALLOTRANSPLANTATION OF DUCT LIGATED SEGMENTS. (Eng.) Kyriakides, G. K.; Arora, V. K.; Lifton, J.; Nuttall, F. Q.; Miller, J. (Veterans Admin. Hosp., 54th St. and 48th Ave. South, Minneapolis, MN 55417). *J. Surg. Res.* 20(5):461-466; 1976.

The effects of glucagon, methylprednisolone, and azathioprine, either alone or in various combinations, on factors complicating segmental pancreatic allografts were studied. Segmental duct-ligated pancreatic allografts were performed in female pigs. Control, untreated grafts underwent significant destruction secondary to inflammation and rejection within 2 weeks of transplantation. In contrast, treatment with methylprednisolone (1 g/day, i.m.) prevented these changes and preserved both the endocrine and exocrine functions of the allografts. Because of continuing exocrine function, large quantities of amylase-rich peripancreatic fluid accumulated and became secondarily infected. The addition of glucagon (4 mg twice daily, i.m.) to this regimen significantly inhibited exocrine pancreatic function and prevented fluid accumulation and peripancreatic abscess formation. In animals treated with methylprednisolone alone or in combination with azathioprine (5 mg/kg), the mean serum levels of amylase at sacrifice (2,167 and 2,621 U/100 ml, resp.) were significantly higher than levels before transplant (1,150 and 1,355 U/100 ml, resp.); in the groups treated with Solu-Medrol plus glucagon or with methylprednisolone, glucagon, and azathioprine, there were no significant differences in the serum amylase levels before transplant (1,270 and 1,551 U/100 ml, resp.) and at sacrifice (1,717 and 2,070 U/100 ml, resp.). In conclusion, methylprednisolone prevents the inflammation, fibrosis, and rejection of duct-ligated pancreatic allografts, but allows large quantities of amylase-rich peripancreatic fluid to accumulate and become infected. This can be prevented by glucagon administration, which inhibits the exocrine pancreatic function.

DIAGNOSTIC PROCEDURES

5519 ENDOSCOPIC COMPLICATIONS. RESULTS OF THE 1974 AMERICAN SOCIETY FOR GASTROINTESTINAL ENDOSCOPY SURVEY. (Eng.) Silvis, S. E.; Nebel, O.; Rogers, G.; Sugawa, C.; Mandelstam, P. (Veterans Admin. Hosp., 54th St. and 48th Ave., Minneapolis, MN 55417). *JAMA* 235(9):928-930; 1976.

A survey of complications resulting from endoscopy was carried out. Esophagogastroduodenoscopy (211, 410 examinations) had a complication rate of 1.3/1,000 cases. Duodenoscopy with cannulation was performed 3,884 times and had a complication rate of 21.6/1,000 examinations. Diagnostic coloscopy (25,298 examinations) had a complication rate of 3.4/1,000. Polypectomies performed during coloscopy in 6,124 cases had a complication rate of 23.3/1,000 cases. Esophageal dilations (13,139 cases) had a complication rate of 4.25 with mercury bougies, and in 9,431 cases metal olives produced a complication rate of 6.1/1,000 treatments. Dilation for achalasia in 1,224 patients produced a complication rate of 18.4/1,000 procedures. Peritoneoscopy (4,404 examinations) produced a complication rate of 5.4/1,000 patients. The value of these diagnostic and therapeutic procedures is now well established, but must be weighed against a potential risk of complications.

5520 FOLIC ACID ABSORPTION IN VARIOUS GASTROINTESTINAL DISORDERS. (Eng.) Elsborg, L.; Bastrup-Madsen, P. (Univ. Dept. Medicine, Aarhus Amtssygehus, Aarhus C, Denmark). *Scand. J. Gastroenterol.* 11(3):333-335; 1976.

Since folate deficiency originating from malabsorption of folic acid has been previously demonstrated in some patients with gastrointestinal diseases, the folic acid absorption (TRIFA) test was carried out in 133 patients with various gastrointestinal diseases. The subjects ingested 200 μg of tritium-labeled folic acid, followed by an i.m. injection of 15 mg of nonlabeled folic acid. The amount of labeled folic acid was determined in urine collected for 24 hr. Folic acid malabsorption (i.e.,<30%) occurred in 7 of 18 patients with steatorrhea, in 14 of 59 patients with partial gastrectomy, in 1 of 7 patients with regional enteritis, and in 9 of 32 patients with small intestinal resection or short bowel syndrome following shunt operation for obesity. Nine patients with pernicious anemia (investigated after B_{12} treatment) and eight folate-depleted patients with hepatic cirrhosis had normal folate absorption. These results were compared with those of a previously reported series of 64 patients without gastrointestinal disease; folate malabsorption was present in only one, and this was only slightly below the lower normal limit. The results confirm those of other investigators, that malabsorption of folic acid occasionally occurs in gastrointestinal disorders. The TRIFA test is a simple, rapid, and reliable index of folate malabsorption.

5521 AZYGOGRAPHY IN THE RADIOLOGICAL STUDY OF MALIGNANT ESOPHAGEAL TUMORS. (Fre.) Humeau, F.; Gignoux, M.; Plombin, P.; Fourre, D.; Le Roquais, P.; Le Saint, J. N. (Centre Hospitalier Universitaire, Route Lion-sur-Mer, F 14000 Caen, France). *J. Radiol. Electrol.* 56(3):227-234; 1975.

Forty patients with esophageal cancer underwent azygography, by means of selective opacification following catheterization through the femoral vein. The azygos system was completely visualized 19 times. There were 2 failures, 2 normal, and 36 abnormal results. Complications were few and minimal (a phlebitis, a spontaneously regressed fever, a hematoma at the site of puncture, and an abscess at the site of puncture). Azygography can determine neoplasm spread and volume in the mediastinum and the involvement of other structures (right pulmonary artery). It distinguishes between involvement by deviation, compression, invasion, obstruction, and collateral circulation. Radiological and surgical data from 13/14 patients operated on following azygography indicate that this examination can predict difficulties in, or the impossibility of resecting the tumor, between the third and eighth thoracic vertebrae, and in cases of arch involvement, the need for a total esophagectomy with complementary cervical approach. This nontraumatic, simple, and rapid procedure appears to be most accurate in defining a tumor of the middle third of the esophagus; accuracy is less for lower third tumors.

5522 DIAGNOSIS OF BARRETT'S ESOPHAGUS BY PERTECHNETATE RADIONUCLIDE. (Eng.) Mangla, J. C.; Brown, M. (Monroe Community Hosp., 435 E. Henrietta Rd., Rochester, NY 14603). *Am. J. Dig. Dis.* 21(4):324-328; 1976.

The efficacy and safety of pertechnetate radionuclide in the diagnosis of Barrett's esophagus were investigated in four patients with confirmed disease and in six controls. The fasted patients were given ^{99m}technetium (^{99m}Tc; 5.0 mCi, i.v.) as the sodium pertechnetate, and scintigrams were made 20 and 40 min later. In five controls, the images showed a uniform uptake of ^{99m}Tc by the stomach, with a very clear delineation of the shape of the stomach. The minimal uptake in the region of the esophagus was actually in the mediastinal blood vascular pool. In one patient with Barrett's esophagus, the image was normal. This was the only patient who did not reveal the presence of either parietal or chief cells; the mucosa was lined with columnar epithelial cells only. The other three cases of Barrett's esophagus revealed a dense concentration of the isotope in the distal esophagus, extending cephalad to the outline of the stomach uptake. Although there was one false-negative result, the results clearly suggest that pertechnetate scintigraphy is a safe, rapid, atraumatic method for screening Barrett's esophagus. The test is performed in an average time of 90 sec/scintigraphy and a total patient time of 1 hr in the department.

5523 DIAGNOSIS OF PARTIAL GASTRIC DIVERTICULA. (Eng.) Treichel, J.; Gerstenberg, E.; Palme, G.; Klemm, T. (Klinikum Steqlitz der Freie Universitat Berlin, 1 Berlin 45, Hindenburgdamm 30, Germany). *Radiology* 119(1):13-18; 1976.

Five cases of partial (intramural) gastric diverticula observed in four patients and confirmed by endoscopy or operation are described. All diverticula were located on the greater curvature of the antrum. A round or oval pouch with a small neck and typical changes in shape and size represented the diagnostic radiographic features of partial diverticulum. Complete filling of the diverticulum by the injection of a spasmolytic (Buscopan) and the use of the double-contrast method proved to be important for the correct diagnosis in three patients.

5524 BARIUM FINDINGS IN RETROGRADE INTUSSUSCEPTION.

(Eng.) Nunez, D., Jr.; Bjarnason, T.; Schwartz, S. S. (Hosp. St. Raphael, New Haven, CT 06511). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 125(3):717-722; 1975.

Barium findings in four instances of retrograde intussusception are described, and illustrated in three case reports. In a 52-yr-old woman with terminal ovarian carcinoma, an upper gastrointestinal series revealed an intraesophageal mass that was clearly part of the stomach and an intraduodenal mass that was clearly a part of the jejunum. At autopsy, the retrograde intussusceptions were corroborated, and diffuse abdominal carcinomatosis was found. A hypaque enema examination of a 68-yr-old man revealed a sigmoidocolic intussusception. At operation, the retrograde intussusception was easily reduced, and an intraluminal tumor, histologically an adenomatous polyp, was palpated and resected. Plain roentgenograms of the abdomen revealed small bowel obstruction in a 98-yr-old man with a history of hemicolectomy for carcinoma. An internal hernia was found and reduced, but bowel obstruction recurred. Decompression was attempted by means of a Miller-Abbot tube. The tube arrested in the left midabdomen, and meglucamine diatrizoate was injected, demonstrating a retrograde jejuno-jejunal intussusception. At autopsy, a dilated bowel was found along the course of the tube, but not distal to its tip. These cases illustrate two principles of interpretation. When contrast material is administered orad to an antegrade or caudad to a retrograde intussusception, it must first enter the intussusceptum. When barium is administered orad to a retrograde or caudad to an antegrade intussusception, it must first enter the intussuscipiens.

5525 JEJUNAL MUCOSAL ABNORMALITIES IN PATIENTS WITH RECURRENT APHTHOUS ULCERATION.

(Eng.) Ferguson, R.; Basu, M. K.; Asquith, P.; Cooke, W. T. (Nottingham General Hosp., Nottingham, England). *Br. Med. J.* 1(6000):11-13; 1976.

Because there is a known association between oral ulceration, diarrhea, and weight loss, and because the incidence of recurrent aphthous ulceration is high in idiopathic steatorrhea and celiac disease, the jejunal mucosa of 33 patients with recurrent aphthous stomatitis was examined. Eight patients had biopsy specimens that revealed a flat mosaic appearance, compatible with celiac disease. Only three patients had completely normal biopsies. In the lamina propria, the plasma cell counts in the nonceliac patients with aphthous ulcers were significantly increased (mean=2,064 cells) in comparison with those of normal controls (1,050 cells). The counts were also significantly higher in the celiac group (7,020 cells) than in either normal controls or the patients with aphthous ulcers. The numbers of intraepithelial lymphocytes in the nonceliac group were raised (66 cells) compared with those in normal controls (53 cells). The celiac group had significantly more of these cells (113) than both normal controls and the nonceliac group. In the celiac group, both hemoglobin (12.0 g/dl) and folate (15 μg/l) were significantly lower compared with the nonceliac group (13.5 g/dl and 61 μg/l, resp.). In the celiac group, abdominal discomfort, diarrhea, flatulence, and lethargy occurred in 3%, 5%, 3%, and 7%, resp., while the corresponding symptoms occurred in 15%, 11%, 11%, and 12%, resp., of the nonceliac patients. The eight patients in the celiac group were treated for at least 9 months with a gluten-free diet; all had complete remission of symptoms, and the hematological and biochemical values were restored to normal. In all eight patients, the aphthous ulcers completely resolved and did not recur. If patients with a flat mucosa who respond to treatment with a gluten-free diet can be considered to have true celiac disease, there are probably many people with undiagnosed celiac disease. The results indicate the importance of performing jejunal biopsies in patients with recurrent aphthous ulceration.

5526 RADIOGRAPHIC AND ENDOSCOPIC FEATURES OF COLONIC ULCERS IN SYSTEMIC Lupus erythematosus.

(Eng.) Tsuchiya, M.; Okazaki, I.; Asakura, H.; Ohkubo, T. (Keio Univ. Sch. Medicine, 35, Shinanomachi, Shinjuku-Ku, Tokyo, Japan). *Am. J. Gastroenterol.* 64(4):277-285; 1975.

The radiographic and endoscopic features of colonic ulcers in a 29-yr-old woman with systemic *Lupus erythematosus* are described. The patient presented with tenderness of the palpable rigid pelvic colon. She had a 5-month history of loose, watery stools. The results of a physical examination were essentially normal. A barium enema showed multiple small ulcers in the rectal, sigmoid, and descending colon, with preservation of colonic length and haustral marking. The niches of these small ulcers in profile were "collar button" in appearance. Colonofiberscopy and proctoscopy revealed a diffuse, swollen, and cloudy mucosa covered with a yellowish exudate. There were multiple punched-out ulcers, variable in size and depth, and circular or elliptical in shape. A biopsy revealed scattered mucosal and submucosal involvement by nonspecific inflammation. Infiltrates included lymphocytes, plasma cells, and polymorphonuclear neutrophils. Selective angiography of the inferior mesenteric artery showed a slightly dilated rectal artery and the early appearance of dense venous drainage in the rectosigmoidal colon. Steroid and 6-mercaptopurine therapy was an effective treatment. These findings are compared with those of 21 similar cases reported previously. There were two types of intestinal involvement: a predominating vasculitis with resultant ulceration and perforation or bleeding from the bowel, usually associated with a clinical picture suggestive of systemic *Lupus erythematosus* or pathological findings of the usual type of nonspecific ulcerative or granulomatous colitis. Steroid therapy is effective in the treatment of both types.

5527 APPLICATION OF THE IMMUNOELECTROPHORESIS TEST FOR HYDATIDOSIS IN PATIENTS WITH A PRESUMPTIVE DIAGNOSIS OF THE DISEASE. (Eng.) Lopez-Lemes, M. H.; Varela-Diaz, V. M. (Laboratorio de Immunologia Parasitaria, Hospital de Clinicas, Facultad de Medicina, Montevideo, Uruguay). *Trop. Geogr. Med.* 27(3):301-304; 1975.

The immunoelectrophoresis (IEP) test for hydatidosis was modified to obtain results within 48 hr rather than in the standard 5-7 days. The sera of 62 patients with hydatidosis were tested. The slides were incubated for 48 hr, followed by treatment in a citrate solution (modified method). The sera were again tested after the same slides were washed and demineralized in distilled water and stained with Amido Schwartz. Forty-three of 51 sera taken preoperatively were positive by the standard test. In 22 of these, the diagnostic *Echinococcus granulosus* arc 5 was readily recognizable immediately following treatment with the citrate solution. Of the 11 sera taken postoperatively, 10 were positive after staining, and in 5 of these, the diagnostic arc was detected when the staining was eliminated. The results suggest that although the diagnostic arc may not be seen in unstained slides when weakly reactive sera are tested, the slides should be examined following the citrate treatment.

5528 NEW ANGIOTOMOGRAPHIC METHOD FOR THE EXAMINATION OF THE LIVER. ITS VALUE, LIMITS AND CURRENT INDICATIONS--EXPERIENCE WITH 150 CASES. (Fre.) Lamarque, J. L.; Senac, J. P.; Bruel, J. M.; Toulsa, A.; Nicolas, A. (Service Central de Radiodiagnostic, Cliniques St-Eloi, 34000 Montpellier, France). *Med. Chir. Dig.* 3(4):253-259; 1974.

One hundred and fifty angiotomographies of the liver were performed in patients with liver tumors and in normal subjects. In cases of malignant tumors, the tomography clearly showed arterial lesions and confirmed the integrity of one lobe when the other was invaded by metastases. Angiotomography allows topography of the previously unknown spatial arrangement of the segmental arteries of the liver. The extreme clarity and detail of the images permits improved diagnostic accuracy.

5529 GALLSTONE ILEUS: THE IMPORTANCE OF CONTRAST EXAMINATIONS IN THE ROENTGENOGRAPHIC DIAGNOSIS. (Eng.) Balthazar, E. J.; Schechter, L. S. (Metropolitan Hosp. Center, 1901 First Avenue, New York, NY 10029). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 125(2):374-379; 1975.

Experience with 12 elderly (average age, 74 yr) patients in whom contrast medium examinations were more helpful in the diagnosis of gallstone ileus than were plain, supine, and upright abdominal films is presented. Air in the biliary tree was visualized in the plain films of five patients. A faintly calcified, ectopically located gallstone was visualized in only three cases. The small bowel pattern was considered compatible with intestinal obstruction (i.e., dilated small bowel loops, air fluid levels on the upright film, and variable amounts of air within the colon) in six cases. On the basis of the plain abdominal examination, the preoperative diagnosis of gallstone ileus was suggested in only four cases. When examined retrospectively, the seven upper gastrointestinal contrast examinations performed had definite findings, which permitted a positive diagnosis. Four cases demonstrated that the barium-filled gallbladder was a diverticulum-like structure, adjacent to and filling from the first duodenal segment. In one case, a tubular structure representing a cholecystoduodenal fistulous tract was visualized, while in the remaining two cases the entire extrahepatic biliary tree filled with barium. It is concluded that the plain abdominal film may be inconclusive and misleading in cases of gallstone obstruction. Contrast examinations should be performed immediately in elderly patients suspected of small bowel obstruction, even when the scout abdominal film is unremarkable.

5530 INTRAVENOUS HEPATOSPLENOGRAPHY. EXPERIMENTAL EVALUATION OF A NEW CONTRAST MATERIAL. (Eng.) Vermess, M.; Adamson, R. H.; Doppman, J. L.; Rabson, A. S.; Herdt, J. R. (Clinical Center, Building 10, Room 6S211, Natl. Inst. Health, Bethesda, MD 20014). *Radiology* 119(1):31-37; 1976.

A new, lipoid-based experimental contrast material (AG 60-99) was infused i.v. into 29 rhesus monkeys in an effort to opacify the liver and spleen for a period of time that would allow the routine use of tomography and improve the diagnostic accuracy of the examination of these organs. Three animals received dextrose in saline and served as controls. Of the 29 list animals, 20 received one injection, 8 received two injections, and 1 received four injections; the doses were: 1 ml/kg (6 injections), 2 ml/kg (28 injections), 3 ml/kg (2 injections), and 4 ml/kg (4 injections). Satisfactory hepatosplenograms were obtained at 2 ml/kg or more in over 80% of the trials. The injections resulted in dense hepatosplenograms, preserving diagnostic quality for over 24 hr and enabling routine utilization of tomography. This technique demonstrated simulated hepatic masses as small as 5 mm in diameter, which had been implanted in the liver of one animal. Limited histopathologic and toxicity studies showed no serious or lasting toxic manifestations from AG 60-99, and none of the animals died from it. AG 60-99 is potentially useful in the radiographic detection of early metastatic or lymphomatous involvement of the liver and spleen.

5531 LIVER SCANS IN CYSTIC FIBROSIS. (Eng.) Goodchild, M. C.; Banks, A. J.; Drolc, Z.; Anderson, C. M. (Inst. Child Health, Univ. Birmingham, Birmingham B15 2TH, England). *Arch. Dis. Child.* 50(10):813-815; 1975.

The value of liver scans in detecting progressive biliary cirrhosis in cystic fibrosis (CF) was studied in 16 children (aged 7-18 yr) with CF, and the results were compared with those of liver function tests (serum total proteins and albumin, SGOT, SGPT, serum alkaline phosphatase, prothrombin index, WBC count, and platelet count). The liver scans were examined by four observers. Scanning was done 30 min after the i.v. administration of 1 mCi ^{113m}In in colloidal form. A Shwachman score, which gives a measure of the degree of illness in CF by taking into account general activity, physical findings, nutritional status, and chest x-ray appearances, was calculated for each patient. Taking a mean value for the four opinions on each scan, 78% of the scans were thought to be abnormal. No correlation was noted between the degree of abnormality shown by the scans and the ages of the patients or their Shwachman scores. Abnormal liver function tests occurred in only four patients (elevated alkaline phosphatase in 2; elevated SGPT in 1; elevated alkaline phosphatase, abnormal prothrombin index, and reduced platelet count in 1), suggesting that scintiscans can detect an abnormality at a stage when hepatic cell function is still apparently undisturbed. However, the scans did not show liver disease of an unsuspected severity, and they did not allow any modification in treatment. Since no correlations between scan appearances and the ages of the patients or their Shwachman scores were found, the procedure will probably not contribute substantially to the prognosis in CF.

5532 SIGNIFICANCE OF GAMMA-GLUTAMYL TRANSPEPTIDASE IN PANCREATIC AND HEPATOBILIARY PATHOLOGY. COMPARISON WITH THE ALKALINE PHOSPHATASES AND WITH 5'-NUCLEOTIDASE. (Fre.) Touboul, J. P.; Hecht, Y.; Feneant, M.; van Batten, R. (Laboratoire Central de Biochimie "A," Hopital St-Antoine, 184, rue du Faubourg St-Antoine, 75571 Paris Cedex 12, France). *Med. Chir. Dig.* 4(4):227-232; 1975.

Serum activity of gamma-glutamyl transpeptidase (γ-GT), alanine amino transferase (ALAT), alkaline phosphatases (ALP), and 5'-nucleotidase (5'-NT) was studied in 324 patients with pancreatopathies (11), viral hepatitis (31), chronic active hepatitis (4), cirrhosis (65), primary biliary cirrhosis (47), intrahepatic cholestasis (26), extrahepatic cholestasis (29), cancer of the liver (52), and various cancers without hepatic metastases (38). Results indicate that a rise in γ-GT is strongly indicative of a hepatobiliary disorder but cannot lead to a differential diagnosis. However, γ-GT behaves more like a cholestatic enzyme. Compared to ALP and 5'-NT, activity of γ-GT is more varied in hepatobiliary disorders and especially in cholestases. Like ALP and 5'-NT, it cannot differentiate between intra- and extrahepatic cholestasis. Serum levels are high in hepatic cancers, and may be indicative of hepatic metastases.

5533 USE OF CAERULEIN WITH SUBMAXIMAL DOSES OF SECRETIN AS A TEST OF PANCREATIC FUNCTION IN MAN. (Eng.) Ribet, A.; Tournut, R.; Duffaut, M.; Vaysse, N. (Groupe de Recherche de Pathologie Digestive, CHU Rangeuil L3, 31400 Toulouse, France). *Gut* 17(6):431-434; 1976.

To determine the optimal conditions for the use of cerulein in the diagnosis of pancreatic disease, the effect of increasing doses of cerulein on bicarbonate and enzyme (lipase, amylase, and chymotrypsin) secretion was studied in 110 normal controls and 32 patients with pancreatic disease. Fifteen patients had chronic pancreatitis, 13 had recently (within 3-5 weeks) had acute pancreatitis, and 4 had histologically proven pancreatic carcinoma. Thirty-one controls received a continuous infusion of secretin [0.5 clinical units (CU)/kg/hr, i.v.] plus two consecutive doses of cerulein (18, 37.5, 75, and 150 ng/kg/hr). Thirty controls received secretin (2 CU/kg/hr) alone for 1 hr. The rates of bicarbonate secretion equivalent to the response to 2 CU/kg/hr secretin were obtained with all doses of cerulein combined with a background dose of secretin. However, the enzyme-secretory response obtained with 75 ng/kg/hr cerulein was greater than the responses obtained with the two lower doses. Cerulein at 75 ng/kg/hr combined with 0.5 CU/kg/hr secretin was then tested as a stimulant of pancreatic secretion of both bicarbonate and enzymes in 45 controls and the 32 patients with pancreatic disease. The bicarbonate secretory response to secretin plus cerulein in the controls was greater than that in 12 of the patients with chronic pancreatitis, while there was almost complete overlap between the results obtained in controls and those in patients with acute pancreatitis and pancreatic cancer. The separation between chronic pancreatitis and the control group was similar for lipase and chymotrypsin; only two patients with chronic pancreatitis had results that overlapped with those from the controls. The overlap between the outputs of amylase of the two groups precluded the use of amylase secretion for diagnostic purposes. Although the pancreatic secretory response to a combination of cerulein and secretin cannot be used as the sole criterion in the diagnosis of pancreatic carcinoma, the combination of peptides is a safe, reliable, and inexpensive method of establishing the diagnosis of the pancreatic exocrine insufficiency caused by chronic pancreatitis.

5534 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN FAMILIAL PANCREATITIS. (Eng.) Perrault, J.; Gross, J. B.; King, J. E. (Mayo Clinic, 200 First St. SW, Rochester, MN 55901). *Gastroenterology* 71(1):138-141; 1976.

The cases of a father and son in whom endoscopic retrograde cholangiopancreatography (ERCP) was useful in the diagnoses of pancreatitis, presumably of the hereditary type, are presented. In the 20-yr-old son, pancreatitis with calculi was initially diagnosed by roentgenographic and cholecystographic examinations, which revealed large calculi in the head and body of the pancreas. The subsequent demonstration by ERCP of large intraductal stones in the dilated main pancreatic duct provided more complete detail. ERCP was also of value in the 42-yr-old father, because no calculi were seen on the plain abdominal roentgenogram. The finding that the main pancreatic duct was dilated in the father confirmed the diagnosis of pancreatitis. The diagnosis was confirmed in the son at surgery; a side-to-side pancreatojejunostomy 9 cm in length was performed. The patient became asymptomatic, except for persistent steatorrhea, which was controlled by p.o. pancrelipase. A transient episode of weakness and diaphoresis, associated with a decrease in blood glucose to 57 mg/dl, was the only side effect of ERCP in the son, and this may have been related to reactive hypoglycemia after glucagon infusion. Phlebitis of the brachial vein, probably secondary to diazepam use, occurred in the father. The onset of attacks of epigastric pain in childhood in both cases, as well as the lack of gallstones or alcoholic excesses, suggested the possibility that the pancreatitis was of the heritable type. ERCP may be useful in the diagnosis of suspected pancreatitis.

5535 PERFUSION CHOLANGIOGRAPHY. (Fre.) Bismuth, V.; Chalut, J.; Diard, F.; Dijan, A.; Girard, J.; Lamarque, J. L.; Lautrou, J.; May, J. P.; Nahum, H.; Oury, F.; Triquet, O. (Hopital Ambroise-Pare, F92100 Boulogne, France). *J. Radiol. Electrol. Med. Nucl.* 56(8/9):581-589; 1975.

Two types of perfusion cholangiography are reviewed and discussed. Cholangiography with a perfusion of under 2 hr has replaced the rapid i.v. injection and has the same indications and contraindications. It allows simultaneous study of the gallbladder and of the common bile duct, a more constant opacification of the bile ducts, and greater safety. There is lack of agreement on optimal duration of the perfusion and when to block the sphincter of Oddi. A 12-hr-perfusion permits use of cholangiography in new indications, especially in the study of bile ducts in patients with jaundice or hepatic insufficiency. Although the gallbladder is better opacified than the common bile duct, a subsequent fatty meal will produce a good opacification of the latter. The lengthy perfusion presents inconveniences; and surveillance must be extremely strict to avoid complications and to ensure a uniform perfusion.

5536 PHLEBOGRAPHY OF THE PANCREATIC VEINS. (Eng.) Lunderquist, A.; Tylen, U. (Univ. Hosp., S-22185 Lund, Sweden). *Radiologe* 15(5):198-202; 1975.

Experience with transumbilical and percutaneous transhepatic catheterization of pancreatic veins is reported, and the normal venous anatomy, changes occurring in pancreatic carcinoma, and experience with cases in which this technique was combined with hormone assay are discussed. In carcinoma of the pancreas, the pancreatic veins show increased tortuosity and obliterations. Obliteration of a vein can sometimes be difficult to interpret, as the blood flow against the injection of contrast medium may prevent filling of venous branches; in these cases, other pancreatic venous branches must be injected. A large carcinoma may obliterate small veins, making them inaccessible to catheterization; in these cases, changes in the walls of large veins adjacent to the pancreas suggest the diagnosis. In one patient with Zollinger-Ellison syndrome in whom arteriography revealed a single large tumor in the head of the pancreas, transhepatic catheterization of the portal vein in combination with gastrin assay suggested that multiple tumors were present. High gastrin concentrations were found in all veins draining the pancreas, and at operation, insulomas were found in the head, body, and tail of the pancreas. Percutaneous transhepatic catheterization of the veins draining the pancreas, together with the discovery of high insulin concentrations in the anterior-superior pancreatic-duodenal vein and in the splenic and portal veins, suggested the diagnosis in another patient with a benign insulinoma. Percutaneous transhepatic catheterization of the veins in the portal system will presumably be of great value in the diagnosis and localization of endocrine tumors of the pancreas.

5537 EFFECT OF TOTAL GASTRECTOMY ON ACID PROTEOLYTIC ZYMOGENS IN SERUM AND URINE. (Eng.) Ishimori, A.; Sakurada, H.; Kawamura, T.; Hashimoto, H.; Yamagata, S.; Miura, Y.; Tsuda, K.; Yamagata, S. (Tohoku Univ. Sch. Medicine, 1-1 Seiryomachi, [980] Sendai, Japan). *Tohoku J. Exp. Med.* 118(1):45-51; 1976.

5538 ISOLATION OF MONOIODINATED GASTRIN USING DEAE-SEPHADEX AND ITS CHARACTERISTICS IN THE GASTRIN RADIOIMMUNOASSAY. (Eng.) Brown, T. R.; Bagchi, N.; Mack, R. E.; Booth, E.; Jones, D. P. (Hutzel Hosp. Medical Univ., Detroit, MI 48201). *Clin. Chim. Acta* 67(3):321-323; 1976.

5539 THE DIAGNOSIS OF GASTRIC CANCER USING A CATHETER-TYPE SEMICONDUCTOR RADIATION DETECTOR—COMPARISON OF DIAGNOSTIC VALUES OF β-EMITTING RADIONUCLIDE LABEL WITH γ-EMITTING LABEL. (Jpn.) Sassa, R.; Iwase, T.; Sugits, T.; Iio, M. (Inst. Adult Diseases, Asahi Life Foundation, Japan). *Jpn. J. Nucl. Med.* 12(3):255-260; 1975.

5540 MINIMAL THOROTRAST DEPOSITION IN PARA-PANCREATIC LYMPH NODES. (Eng.) Okuda, K.; Ichinohe, A.; Kono, K.; Ueda, S.; Noguchi, T.; Matsuura, Y.; Shimokawa, Y. (Dept. Medicine, Chiba Univ. Hosp., Chiba 280, Japan). *Radiology* 119(1):23-26; 1976.

5541 THE TRYPSIN INHIBITORY ACTIVITY OF PURE HUMAN PANCREATIC JUICE [Abstract]. (Eng.) Elias, E.; Southcott, J.; Marten, A.; Scott, J.; Summerfield, J. A. (Royal Free Hosp., Pond St., London NW3, England). *Gut* 17(5):385; 1976.

5542 ULTRASONIC DIAGNOSIS OF PANCREATIC CONDITIONS: A TENTATIVE RATIONAL APPROACH BASED ON THE ANALYSIS OF 260 CONTROL CASES WHICH WERE CHECKED (WITH REAL TIME AND DEGRADED INTENSITY SCALE). (Fre.) GASTROINTESTINAL DISEASES

ESOPHAGUS

5578 FIBEROPTIC ENDOSCOPIC DIAGNOSIS AND TREATMENT OF A CONGENITAL ESOPHAGEAL DIAPHRAGM. (Eng.) Gilat, T.; Rozen, P. (Ichilov Hosp., Weizmann St., Tel Aviv, Israel). *Am. J. Dig. Dis.* 20(8):781-785; 1975.

The case of a 9-month-old girl in whom fiberoptic endoscopy was used in the diagnosis of a congenital esophageal diaphragm is presented. The infant had dysphagia to solids, and presented with esophageal bolus obstruction. Using an adult fiberoptic esophagoscope, a congenital web was found at the junction of the middle and distal thirds of the esophagus. Previous direct rigid esophagoscopy and roentgenologic examination had not visualized the web. The web was successfully ruptured and dilated by inserting a guide wire under fiberscopic control and then inserting metal olives, followed later by blind mercury bougienage. This case illustrates the use of adult fiberoptic instruments for the diagnosis and treatment of esophageal diaphragm in pediatric patients.

5579 EARLY CARCINOMA OF THE ESOPHAGUS. (Fre.) Marchat, F.; Lambert, R.; Moulinier, B.; (Hopital Edouard-Herriot, Place d'Arsonval, F 69374, Lyon Cedex 2, France). *Lyon Med.* 232(16):323-327; 1974.

Literature on early esophageal cancer is reviewed including survival data on selected cases. Early carcinoma is defined as infiltration of the mucosa and submucosa without invasion of muscle tissue or nodal spread and metastases. There are no characteristic clinical symptoms and, in fact, symptoms are often absent. Early symptoms might be slight difficulty in swallowing, sensation of a foreign body in the throat, retrosternal pain, spasm, etc. Esophageal study should precede medication. Diagnostic approach should begin with radiography followed by endoscopy (esophagoscopy and isotopic esophagoscopy) complemented by biopsy and blind biopsy. Surgery usually confirms the diagnosis. The over-all 5-yr survival rate of patients with esophageal cancer is under 10%. If detected in the early stages, the prognosis is more encouraging. In one series of 52 cases, 21 survived 2 yr or more; survival of 28 patients for more than 2 yr was reported in another series; and in a third series, one 4-yr survival with death from cervical neoplasm, five 4-yr survivals with death from other diseases, and 5-yr survival for 21/43 patients were reported.

5580 COLUMNAR CELL-LINED ESOPHAGUS: ASSESSMENT OF ETIOLOGY AND TREATMENT: A 22 YEAR EXPERIENCE. (Eng.) Borrie, J.; Goldwater, L. (Otago Medical Sch., Dunedin, New Zealand). *J. Thorac. Cardiovasc. Surg.* 71(6):825-834; 1976.

The clinical patterns, methods of management, and long-term results of treatment were studied in 45 patients with proven columnar-lined esophagus (CLE). Twenty-one patients were male and 24 female, with bimodal age ranges peaking in the decades 0-10 and 48-80 yr. Of the first decade patients, all boys, two were brothers. While 44 had dysphagia, one third also had iron-deficiency anemia. All had x-ray-proven sliding hiatal hernias, with esophageal stricturing at the squamous cell-columnar cell interface. In 43 cases, this area was 35 cm or less from the upper jaw. The epithelial histology showed simple, tubular, mucus-secreting glands in 45 cases, goblet cells in 7 cases, no goblet cells in 38 cases, and gastric-type epithelium with parietal cells in 19 cases. In two cases, CLE was rising up the esophagus from 35 to 30 cm in 3 yr and from 40 to 23 cm in 10 yr. No stricture became neoplastic. The clinical evidence supports the view that CLE has a double etiology: it is congenital in children, but acquired, akin to "intestinalization of the stomach," in adults with sliding hiatal hernias. In the latter instance, CLE occurs as an alternative endpoint to reflux esophagitis. All patients had initial stricture dilatation with biopsy. In 17, this was the sole treatment. In 16 cases, a later transthoracic herniorrhaphy was performed to reduce the hiatal hernia and prevent further stricturing. Fifteen patients had transmural strictures. For this group, the authors' experience with Roux-Y esophagogastrostomy and esophagojejunogastrostomy, with stricture excision, and also with mere bypass of the stricture is reported. For the young, after stricture excision, esophagojejunogastrostomy with pyloroplasty performed in the second decade is favored. In the elderly, especially after unsuccessful hiatal herniorrhaphy, esophagojejunogastrostomy with stricture bypass proved satisfactory 3 yr after the operation.

5581 LOCALIZED PROXIMAL ESOPHAGITIS SECONDARY TO ASCORBIC ACID INGESTION AND ESOPHAGEAL MOTOR DISORDER. (Eng.) Walta, D. C.; Giddens, J. D.; Johnson, L. F.; Kelley, J. L.; Waugh, D. F. (Tripler Army Medical Center, Honolulu, HI). *Gastroenterology* 70(5):766-769; 1976.

The case of a 24-yr-old woman with an esophageal motor disorder, who experienced localized proximal esophagitis after ingesting a 500-mg ascorbic acid tablet, is presented. The patient presented with retrosternal chest pain and odynophagia. Fiberoptic esophagoscopy performed 8 hr after the ascorbic acid ingestion showed esophagitis, manifested by erosions and exudate 26 cm from the incisor teeth in the region of the aortic arch. Biopsy showed a severely inflamed lamina propria. A subsequent esophageal manometric study showed a mean distal esophageal sphincter pressure of 29 mm Hg and discoordinate aperistaltic contractions. An animal model confirmed the caustic nature of ascorbic acid for esophageal mucosa. In one healthy dog and two cats, a modified Mallinckrodt catheter held a control calcium lactate tablet 6 cm orad from a 500-mg ascorbic acid tablet, which was placed at the junction of the middle and lower third of the esophagus. After 24 hr, the esophagi of all animals were similar to that of the patient. The epithelium in the region of tablet was infiltrated with polymorphonucleated leukocytes, with areas of epithelial ulceration and edema, and the lamina propria contained areas of necrosis. The aperistaltic contractions in the patient probably caused prolonged mucosal contact of the ascorbic acid tablet in the region of the aortic arch and permitted a low intensity caustic agent to cause esophagitis.

5582 EXPERIENCES WITH THE LINTON-NACHLAS AND THE SENGSTAKEN-BLAKEMORE TUBES FOR BLEEDING ESOPHAGEAL VARICES. (Eng.) Burcharth, F.; Malmstrom, J. (Gentofte Hosp., Copenhagen, Denmark). *Surg. Gynecol. Obstet.* 142(4):529-531; 1976.

A controlled clinical trial was carried out to compare the effectiveness of the Sengstaken-Blakemore tube with that of the Linton-Nachlas tube in the emergency treatment of esophageal varices. Twenty-eight patients who had a total of 42 bleeding episodes were included in the study. Nine patients had previously been treated with the Sengstaken-Blakemore tube, and the remaining patients had not previously been treated by balloon tamponade. If rebleeding occurred during the same admission in which a patient was being treated with one of the tubes, treatment with the opposite type of tube was instituted. Twenty-seven bleeding episodes were treated with the Sengstaken-Blakemore tube, with bleeding being controlled in 20, and 15 were treated with the Linton-Nachlas tube, with bleeding being controlled in 6. No significant difference was found between the two types of tubes ($0.05<p<0.1$). During 27 treatments with the Sengstaken-Blakemore tube, five patients experienced respiratory distress due to dislocation of the tube, which was easily treated by deflation of the balloon. During the 15 treatments with the Linton-Nachlas tube, complications were caused by inflation of the balloon erroneously placed in the distal part of the esophagus; this caused rupture of the esophagus in two patients, and both died despite thoracotomy and suture. The study was terminated after the death of the second patient. The results suggest that the use of the Sengstaken-Blakemore tube is preferable to that of the Linton-Nachlas tube, except in the rare instances in which a hiatal hernia renders the Sengstaken-Blakemore tube liable to displacement, or bleeding from fundic varices renders it ineffective.

5611 ENDOSCOPIC INDUCTION OF THE ELECTROMYOGRAM FROM THE HUMAN GASTROINTESTINAL TRACT.

(Eng.) Akasaka, Y.; Niki, I.; Sugawara, K.; Kawai, K. (Dept. Internal Medicine, Gifu Coll. of Dentistry, Monzen-cho, Naka-cho, Inaba-Gun, Gifu-ken, Japan). *Endoscopy* 7(3):139-141; 1975.

A new method of obtaining electromyograms of gastric and duodenal peristaltic movements using endoscopy is presented. The endoscope is inserted into the stomach or duodenum, and an electrode is vertically pierced into the gastric or duodenal wall. The electromyograms were recorded from the stomach (pyloric ring, antrum, and the lower part of the body) in 6 healthy volunteers and from the duodenum (the bulb and the second portion) in 18 volunteers. In the stomach, the grouped spikes regularly appeared at the interval of 10-24 sec. The greatest amplitude of grouped spikes averaged 0.2 mV, and their duration averaged 3 sec. In the duodenum, the grouped spikes occurred regularly at an average interval of 6 sec. The greatest amplitude of grouped spikes averaged 0.1 mV, and their duration averaged 1.8 sec. When acetylcholine chloride (0.2 mg/kg) was injected i.m., the number and amplitude of the grouped spikes of the duodenum increased, and the average interval was shortened markedly. After the i.v. injection of scopolamine butylbromide (0.4 mg/kg), there was a marked decrease in the number and amplitude of the grouped spikes, and the average interval was prolonged. The qualities of these electromyograms are similar to those of the electromyograms taken by previously reported methods.

5612 SERUM PYRIDOXAL IN PATIENTS WITH GASTRIC PATHOLOGY.

(Eng.) Sanderson, C. R.; Davis, R. E. (Royal Perth Hosp., Wellington St., Perth, Western Australia). *Gut* 17(5):371-374; 1976.

Studies were carried out in 8 normal controls and in 60 patients with gastric diseases other than peptic ulcers to investigate whether a low serum pyridoxal value is unique to peptic ulceration or if it occurs in other types of gastric pathology. Serum pyridoxal values were also compared with folate values in these subjects. There were 25 men and 35 women, and their ages ranged between 41 and 89 yr (mean 64 yr). Sixteen patients had gastric carcinomas, 6 had benign polyps, 9 had superficial gastritis, 19 had atrophic gastritis, and gastric atrophy was present in 2 patients. Serum pyridoxal levels were below normal in 44 patients. Of 13 patients with a folate level below 2.5 µg/l, 12 had a serum pyridoxal level of 12 or less. However, in 26 patients with a serum pyridoxal level of this order, serum folate varied between 0.9 µg/l and 15.5 µg/l. Serum folate was normal in all eight controls, and pyridoxal was low in one. The results show that a low serum pyridoxal level is not restricted to patients with active gastric ulceration. Dietary insufficiency, malabsorption, increased utilization or excretion, or any combination of these factors, could be responsible for the low serum pyridoxal levels found in the majority of patients with gastric pathology.

5613 GASTRIC MORPHOLOGY AND SERUM GASTRIN LEVELS IN PERNICIOUS ANAEMIA.

(Eng.) Lewin, K. J.; Dowling, F.; Wright, J. P.; Taylor, K. B. (Dept. Pathology, Room L235, Stanford Univ. Medical Sch., Stanford, CA 94305). *Gut* 17(7):551-560; 1976.

The range of gastric mucosal appearances was studied in 18 confirmed and 3 suspected cases of chronic atrophic gastritis of the type associated with Addisonian pernicious anemia; it was examined in relation to changes in secretory functions in the gastric body and pyloric antrum and the presence of circulating gastric antibodies. Biopsies taken from the body of the stomach and pyloric antrum were examined for gastrin activity by radioimmunoassay. Fasting serum gastrin activities ranged from 100 to 4,000 pg/ml. Serum gastric antibodies were within the expected range. The biopsies showed an epithelium lined by columnar cells and occasional small papillary projections around gland orifices, but there were occasional small foci where the columnar epithelium was replaced by low cuboidal epithelium. The intensity of inflammation was greater in the body than in the pyloric antrum and was generally of moderately severe degree. Inflammatory cells were largely plasma cells and lymphocytes, but there were occasional eosinophils. Atrophy of the fundus was generally severe, while that of the pyloric antrum was mild to moderate. Metaplastic changes were almost universal in the fundus and consisted of small intestinal and pyloric epithelium. The histological changes showed minimal variation from one area of the gastric body to another in multiple biopsies and in repeat samples. Endocrine cells were noticeably increased in eight cases, but this was not consistently related to elevated gastrin levels. The results indicate that the changes in chronic gastritis with pernicious anemia generally involve the entire gastric mucosa, so a single biopsy can reflect the general state of the stomach mucosa, and that metaplastic changes are frequent, particularly in the pyloric antrum.

5614 PRIMARY GASTRIC CANDIDIASIS IN UNCOMPROMISED SUBJECTS.

(Eng.) Nelson, R. S.; Bruni, H. C.; Goldstein, H. M. (M. D. Anderson Hosp. and Tumor Inst., 6723 Bertner, Houston, TX 77025). *Gastrointest. Endosc.* 22(2):92-94; 1975.

Two cases of primary gastric candidiasis occurring in otherwise uncompromised patients are presented. The first patient, an 83-yr-old woman, had a history of diverticulitis, atrophic gastritis, and gastric ulcer. At diagnosis by gastroscopy and cytologic examination of the biopsy specimen, she was essentially healthy, and her only complaint was of epigastric distress. The second patient, a 56-yr-old woman, had had a gastric resection earlier and had had localized perfusion with phenylalanine mustard 4 yr previously; there was no evidence that either of these factors played a part in the infection. In both patients, the earliest changes in gastric moniliasis resembled those of elevation of the mucosa, with ulceration of the apices. In the first patient, p.o. mystatin was ineffective in eliminating the infection, resulting in wider dissemination of involvement and ulceration. A follow-up gastroscopy showed complete healing 1 month after treatment with amphotericin B (5 mg by infusion daily for 3 days followed by 10 mg daily for the next 3 days). In the second patient, the involvement was minimal and never progressed to ulceration after treatment with p.o. mystatin. The correlation of endoscopic and radiological findings was poor in the early stages of infection, and good during the later phase of ulceration. In both patients, the early lesions were never demonstrated by x-ray, although they were readily seen and biopsied at endoscopy. In the first patient, the radiologic and endoscopic findings were completely compatible during the ulcerative phase. At least two target or bull's eye lesions were noted. The radiographic findings appeared to demonstrate deeper ulceration than did endoscopy in this late phase, in which the ulcerations seem rather shallow. Early lesions will be more accurately diagnosed by gastroscopy, biopsy, and cytology.

5615 LACTOFERRIN DEFICIENCY OF GASTRIC JUICE IN CANCER OF THE STOMACH. (Eng.)

Ghetie, A.; Dejica, D.; Abrudan, O.; Diaconescu, S. (Dept. Internal Medicine, City Hosp., Piatra Neaml, Rumania). *Rev. Roum. Biochim.* 12(3):167-169; 1975.

The concentration of lactoferrin was studied in the gastric juice, tumoral tissues, and juxtatumoral gastric mucosa of 26 patients with gastric adenocarcinoma, in 2 patients with gastric ulcer, and 2 healthy subjects. Lactoferrin was not detected by electroimmunodiffusion in the gastric juice of the patients with cancer. It was present in both the gastric ulcer patients and the normal controls, although the concentration varied widely between these subjects. Immunohistological studies demonstrated that lactoferrin was also absent in tumor tissue. The fluorescence corresponding to lactoferrin in the samples taken from around the tumor site was marked, and was similar to that seen in gastric mucosa from the healthy subjects and from the gastric ulcer patients. The absence of lactoferrin in the gastric juice and tumor tissue of patients with gastric adenocarcinoma may be due to an inhibition of lactoferrin delivery from synthesizing sites, neutralization of lactoferrin in the gastric juice, or the inability of the techniques used to detect lactoferrin.

5616 LONG-TERM PROGNOSIS OF IDIOPATHIC GASTRIC EROSIONS. (Eng.)

Walk, L. (Radjurstigen 44, S-17172 Solna, Sweden). *Radiologe* 15(9):356-359; 1975.

The long-term prognosis of multiple gastric erosions (erosive gastritis) was studied in 58 patients who were followed roentgenologically for 10-17 yr. In the six patients aged 18-30 yr, the erosions that recurred were regular and diffusely spread in the antrum. In the remaining patients, who were over 30 yr, the erosions were often irregular in size and appearance, and solitary large erosions were found in five patients. Among 21 patients in whom erosions were seen at the end of the follow-up, erosions were diffusely spread in the antrum and in 12 patients, were arranged either in groups or rows. In two patients, diffuse swelling was present; three had nodular elevations; large erosions were seen in two; in one, a transverse fold in the distal antrum was seen; and a marked knob-like thickening of the antral folds, which had been present for 15 yr was seen in one. Twenty-seven of the 58 patients have been asymptomatic on an ulcer regimen. In the first year of follow-up, there were recurrences in two-thirds of cases. Partial gastric resection was performed in 19 cases. Of three cases in whom erosions were the only lesion, one has been operated upon for repeated bleeding and two for epigastric complaints. Dumping appeared in two patients.

5617 ACUTE GASTRIC MUCOSAL ULCEROGENESIS IS DEPENDENT ON THE CONCENTRATION OF BILE SALT.

(Eng.) Ritchie, W. P., Jr.; Shearburn, E. W., III (Univ. Virginia Medical Center, Charlottesville, VA 22901). *Surgery* 80(1):98-105; 1976.

Bile salt reflux was studied in 11 patients after surgery to determine whether the animal studies implicating bile salt reflux in the formation of stress ulcers are valid in humans. Nine patients refluxed bile salts in a mean intragastric concentration of 1.87 ± 0.24 mM (range: 0.34-4.88 mM), and the ulcerogenic potential of physiologic concentrations of bile salts was evaluated. Using vascularized, chambered canine gastric mucosa, groups of animals were studied during three consecutive 30-min periods. Animals in group A were subjected to the topical acid test (ATS) during all three test periods. Group B was given ATS during periods 1 and 2, and ATA plus vasopresin (VP; 0.1 U/kg/min, via the splenic artery) during the third period. Group C received ATS during the first period, ATS plus topical sodium taurocholate (TC; 1 mM) during the second period, and ATS, TC, and VP during the third period. Group D received ATS during the first period, ATS plus 2 TC during the second period, and ATS plus 2 TC plus VP during the third period. Finally, group E received ATS during the first period, ATS plus 5 TC during the second period, and ATS plus 5 TC plus VP during the third period. The net fluxes of H^+ and Na^+, the electrical potential difference (PD), aminopyrine clearance, and formation of lesions were evaluated. In nonischemic mucosa, bile salts produced no ulcers, but did produce a significant concentration-dependent increase in H^+ back-diffusion [$y=(-76.7 + 115.3x)$, $r=0.87$, $p=0.01$] and a fall in PD [$y=65.0 - 7.6x$, $r=0.96$, $p<0.01$], and a nonconcentration-dependent increase in mucosal blood flow. In ischemic mucosa, the combination of topical acid, topical bile salts, and mucosal ischemia was acutely ulcerogenic. The severity of mucosal injury was dependent on the concentration of bile salt ($y=0.108 + 1.53x$, $r=0.90$, $p<0.01$). The data indicate that acute mucosal damage occurs in the presence of physiologic concentrations of bile salt, i.e., those routinely found in the gastric contents of postoperative patients.

5618 SEPTIC COMPLICATIONS FOLLOWING GASTRIC SURGERY: RELATIONSHIP TO THE ENDOGENOUS GASTRIC MICROFLORA. (Eng.) Nichols, R. L.; Miller, B.; Smith, J. W. (Chicago Medical Sch., Downey, IL). *Surg. Clin. North Am.* 55(6):1367-1372; 1975.

The qualitative microflora isolated from both normal and pathologic stomachs, and its origin and regulatory factors are discussed. The gastric microflora of 43 patients who underwent elective or emergency abdominal surgery was studied. Ten patients had no gastric or duodenal pathology, while the other 33 had either chronic duodenal ulcer, obstructing or bleeding duodenal ulcer, or carcinoma. An 18-gauge needle with a 50-ml syringe was used to perform needle aspiration on the greater curvature of the stomach following surgical entry of the peritoneal cavity. In 22 patients with either a normal stomach or chronic duodenal ulcer, the inhibitory effect of gastric acid and normal motility were evident. Aerobic bacteria were isolated in only five of these patients, and anaerobic bacteria were isolated in two. In contrast, in the 21 patients with carcinoma, bleeding or obstructing duodenal ulcer, or gastric ulcer, the amount of microflora increased greatly. Aerobic bacterial growth was found in all of these patients, and anaerobic growth was discovered in 16. No wound infections occurred among the 12 patients treated for chronic duodenal ulcer; five infections occurred among the other 31 patients. Four of these were shown to have been caused by a microorganism isolated from the initial gastric aspirate. The reduction in gastric acid levels or the alteration in gastric motility in disease states appears to allow the endogenous microflora to persist and to become the source of postoperative wound infections following gastric resection.

STOMACH

Peptic Ulcers

5665 CLINICAL AND EXPERIMENTAL STUDIES ON THE INFLUENCE OF NEUROPLEGIC DRUGS ON GASTRIC SECRETION AND PEPTIC ULCERS. (Pol.) Moczurad, K. (Clinic General Cardiology, Inst. Internal Medicine, Acad. Medicine, Krakow, Poland). *Folia Med. Cracov.* 16(4):413-426; 1974.

The effect of neuroplegic drugs (fenactylcitrate and mepazine) on gastric secretion and on the development of peptic ulcers was studied in 16 male patients with duodenal ulcers, before and after vagotomy, in 60 healthy controls, and in 36 cats (1.8-2.5 kg). The gastric secretion in humans and in cats was stimulated by an i.v. infusion of histamine (20 μg/kg/hr) or pentagastrin (6 μg/kg/hr). Experimental peptic ulcers were induced in cats by an i.v. infusion of histamine (80 μg/kg/hr) or pentagastrin (16 μg/kg/hr). After treatment with fenactylcitrate (1.0 mg/kg) or mepazine (2.0 mg/kg), a statistically significant decrease of secreted HCl was observed in humans and cats; a less significant decrease of secreted HCl was observed in patients after surgical vagotomy and in cats with parasympathetically denervated Heidenhain pouches. The number and surface area of experimental peptic ulcers decreased considerably after drug treatment. This inhibitory effect of neuroplegic drugs on gastric secretion and on the development of peptic ulcers is attributed to the drugs' central action through the vagus nerve, as well as to the direct effect of the drugs on peripheral nerve endings and on the secretory cells of the gastric mucosa.

5666 EFFECT OF A HISTAMINE H_2-RECEPTOR ANTAGONIST AND AN ANTICHOLINERGIC ON GASTRIC ACID SECRETION IN MAN. (Eng.) Barbezat, G. O.; Bank, S. (Groote Schuur Hosp., Cape Town, South Africa). *S. Afr. Med. J.* 50(22):849-853; 1976.

Because of the hypothesis that the parietal cell has separate receptors for histamine, acetylcholine, and gastrin, and that these receptors interact, the effect of blocking the histamine and acetylcholine receptor sites on gastric acid secretion was studied in six patients with duodenal ulcers. Following the collection of basal gastric secretions, pentagastrin (6 μg/kg/hr, i.v.) was infused for 1 hr, and the secretions were again collected. Pentagastrin was discontinued, and one of the following solutions was administered by nasogastric tube: tritiated metiamide (200 mg) in 100 ml of 0.03 M HCl, propantheline bromide (30 mg) in 100 ml of 0.03 M HCl containing ^{14}C-polyethylene glycol (PEG) as marker, or metiamide plus propantheline bromide in HCl containing PEG. All three treatments reduced basal and stimulated-volume output, acid concentration, and acid output. With metiamide, the mean decreases in basal and stimulated-volume outputs were 44.4% and 42.6%, resp.; in acid concentrations, 86.2% and 26.4%, resp.; and in acid outputs, 80.8% and 55.9%, resp. With propantheline, the decreases in basal and stimulated-volume outputs were 28.3% and 37.2%, resp.; in acid concentrations, 48.7% and 22.1%, resp.; and in acid outputs, 69.3% and 51.9%, resp. With the drug combination, the decreases in basal and stimulated-volume outputs were 68.2% and 60.6%, resp.; in acid concentration, 48.2% and 19.4%, resp.; and in acid output, 82.8% and 63.9%, resp. Although the combination of metiamide and propantheline produced a greater inhibition of volume, and consequently of acid output, than each of the drugs alone, only the inhibition of stimulated-volume secretion was significantly greater ($p<0.05$) with combination therapy. It is doubtful that there is any therapeutic advantage from the use of this drug combination in the conventional doses used in this study.

5667 ALTERED SERUM GASTRIN LEVELS IN ACHLORHYDRIC STATES. (Eng.) Turnipseed, W. D.; Keith, L. M., Jr. (Ohio State Univ. Hosp., 410 W. Tenth Ave., Columbus, OH 43210). *Am. J. Surg.* 131(2):175-177; 1976.

Studies were carried out in 15 patients with histamine-fast achlorhydria (6 with pernicious anemia and 9 with atrophic gastritis) to determine the effect of calcium and secretin infusion on serum gastrin concentrations in these patients and to confirm the relationship between altered gastric pH and hypergastrinemia in achlorhydric states. The gastric pH in the achlorhydric patients ranged from 6.0 to 8.1 (mean 7.1 ± 0.2), whereas mean pH in 15 control patients was 1.9 ± 0.1. The basal gastrin levels in the achlorhydric patients were significantly higher than in controls (891 pg/ml ± 282 versus 84 pg/ml ± 8). The basal gastrin levels in three achlorhydric patients with antral gastritis averaged 197 ± 19 pg/ml, whereas the levels in 10 achlorhydric patients without antral gastritis averaged 1,509 ± 426 pg/ml. In the absence of antral gastritis, the mean basal gastrin values were 1,825 ± 63 pg/ml in four patients with pernicious anemia and 1,192 ± 620 pg/ml in six patients with atrophic gastritis. When eight normal controls, three achlorhydric patients with pernicious anemia without antral gastritis, two achlorhydric patients with pernicious anemia and antral gastritis, one achlorhydric patient with atrophic gastritis without antral involvement, and two achlorhydric patients with atrophic gastritis and antral involvement were challenged with an i.v. calcium infusion (4 hr), there was a greater than 200% increase in gastrin levels in the three patients with pernicious anemia without antral gastritis. No response occurred in the other groups. The results indicate that severe basal hypergastrinemia is not confined to the Zollinger-Ellison syndrome, but frequently occurs in achlorhydric patients with pernicious anemia or atrophic gastritis. When the antrum is affected by gastritis, the gastrin levels are much lower; impairment of the acid inhibition reflex may play an important role in the mechanism. The dramatic response to calcium stimulation in patients with pernicious anemia also suggests the possibility that cells with endocrine-like autonomy may exist in the gastric mucosa, and that calcium infusion may be useful in confirming the diagnosis of pernicious anemia.

5668 A COMPARISON OF THE COURSE OF THE DISEASE AMONG PATIENTS WITH GASTRIC ULCER, DUODENAL ULCER, AND ULCER DYSPEPSIA WITHOUT ULCER DEMONSTRABLE BY X-RAY. (Eng.) Viskum, K. (Lungemedicinsk afdeling, Vejle sygehus, Kabbeltoft 25, 7100 Vejle, Denmark). *Dan. Med. Bull.* 23(3): 129-136; 1976.

Duodenal ulcer, gastric ulcer, and ulcer dyspepsia without ulcer demonstrable by x-ray were studied in 2,619 patients during 1938-1952, and 1,331 of these were followed up during 1970-1971. There was little difference in the age distribution between the sexes; ages 41-60 yr were over-represented, while ages 15-30 yr were under-represented. In all three ulcer groups, men were more frequently affected than women. Of the 2,619, 935 underwent surgery for ulcer and on an average of 5.5 yr after index admission. The peak incidence of surgery occurred in the fifth decade of life. The percentage of operations was highest for duodenal ulcer, followed by gastric ulcer and no ulcer. The percentages were higher for men than for women. The main cause for surgery was inability to work due to recurrent symptoms. After surgery, 115 patients had to be reoperated for various reasons; their distribution was not dependent on the indication for the first operation. The preferred first operation was the Billroth II resection. The most common cause for reoperation was the recurrence of pain or hemorrhage (47%). In comparable groups, men had ulcer perforation more frequently than women; it was also more frequent in those who had undergone surgery. Of patients with melena and/or hematemesis, there were no significant differences between men and women, operated and unoperated patients, or among the three ulcer groups. When the total number of admissions due to ulcer disease were tabulated in relation to the number of observation years, the indices of patients prior to surgery were significantly greater than for those not operated on for all three groups. The indices before surgery were significantly greater than those after surgery. Comparison of the course of disease in the three groups from admission to follow-up or death showed that the no ulcer group had a more benign course. Differences between the duodenal and gastric ulcer groups were smaller, however, and the gastric ulcer group had a higher number of patients with no symptoms after admission, fewer who had surgery, and more deaths from ulcer disease. The results indicate that the quantitative differences between the three groups with regard to age at onset, age at admission, and frequency of perforations are moderate, and do not support the idea that the three ulcer groups represent three separate entities.

5669 EVOLVEMENT OF A NEW TREATMENT FOR PERFORATED DUODENAL ULCER. (Eng.) Jordan, P. H., Jr.; Korompai, F. L. (Baylor Coll. Medicine, Houston, TX). *Surg. Gynecol. Obstet.* 142(3):391-395; 1976.

To test the hypothesis that vagotomy and drainage may be a more effective procedure in the therapy of perforated duodenal ulcer than vagotomy and hemigastrectomy, an 8-yr randomized, prospective study was performed on 157 patients. The condition of the patient dictated that 40 patients (those with complications or those with perforation of more than 24-hr duration) be treated by simple closure. In the remaining patients, vagotomy and drainage (55 patients) or vagotomy and hemigastrectomy (62 patients) were performed. These patients were observed postoperatively for an average of 4 yr. There was one operative death after vagotomy and hemigastrectomy and none after vagotomy and drainage. There were no instances of incapacitating diarrhea in either group, and the frequency of postoperative gastric complaints were essentially the same in both groups. The most common postoperative complaints were postprandial fullness, which occurred in 8 of 55 patients after vagotomy and hemigastrectomy, and epigastric distress of various types, including pain, which occurred in 13 of 49 patients after vagotomy and drainage. Mild diarrhea occurred occasionally in 5 of 49 patients after vagotomy and drainage and in 2 of 55 patients after vagotomy and hemigastrectomy. Reoperation was required in three patients after vagotomy and drainage and in one patient after vagotomy and hemigastrectomy. The anticipated advantage of decreased gastric complaints after vagotomy and drainage compared with their frequency after vagotomy and hemigastrectomy in the definitive treatment of perforated duodenal ulcer was not apparent. To provide protection against further ulcer disease, and, at the same time, reduce postoperative gastric sequelae, parietal cell vagotomy without drainage was performed and evaluated in 13 patients with perforated duodenal ulcer. The longest follow-up period for these patients was 2 yr. There was no diarrhea, dumping, or other significant gastric complaint. Gastric emptying was normal, and no ulcers have recurred. The results were excellent in 11 patients and good in 2. These early results suggest that parietal cell vagotomy without drainage may be a satisfactory compromise between the use of simple closure that does not protect patients against recurrent ulcer and the use of vagotomy and hemigastrectomy or vagotomy and drainage, which impose increased morbidity and death rates on those patients who might not have had further ulcer disease.

5670 CIMETIDINE IN THE TREATMENT OF ACTIVE DUODENAL AND PREPYLORIC ULCERS. (Eng.) Bodemar, G.; Walan, A. (Univ. Hosp., 581 85 Linkoping, Sweden). *Lancet* 2(7978):161-164; 1976.

To determine whether cimetidine decreases ulcer pain and promotes healing as well as metiamide, a double-blind trial was carried out in 44 patients with endoscopically confirmed duodenal (36) or prepyloric (8) ulcers. Thirty patients received 200 or 300 mg of cimetidine four times daily for 6 weeks; 14 patients received a placebo for the same period. At 3 weeks, 67% of the patients treated with cimetidine and 17% of those receiving placebo had endoscopically healed ulcers ($p<0.005$). At 6 weeks, all but three patients receiving cimetidine (90%) had healed ulcers, compared with 36% receiving placebo ($p<0.001$).

Twelve patients receiving the 200-mg dose had healed ulcers at 6 weeks, compared with 14 receiving the 300-mg dose. Those receiving cimetidine had less daytime and nocturnal pain than patients on placebo. The differences were statistically significant for daytime pain during 4 of the 6 weeks. The cimetidine-treated patients consumed significantly less antacids than placebo-treated patients, and these patients' overall assessments of their wellbeing were significantly better. All patients on cimetidine had a significant reduction ($p<0.0005$) of their basal and pentagastrin-stimulated acid secretion, but no reduction in acid secretion was measured in the group who received placebo. The results suggest that cimetidine may be effective in the treatment of duodenal ulcer, although controlled, long-term studies are necessary to determine its safety and long-term effectiveness.

5671 BLEEDING FROM EXCLUDED ULCERS OF THE DUODENAL STUMP. (Rus.) Olshanskyi, A. A. (Dnepropetrovsk Medical Inst., Dnepropetrovsk, USSR). *Khirurgiia (Mosk.)* (4):122-125; 1975.

The difficulties in the diagnosis and surgical treatment of bleeding, excluded ulcers of the duodenal stump are reviewed. Exclusion surgery (a partial resection of the stomach) is often performed as a substitute for radical surgery for bleeding ulcers, when the possibility of damage to the general biliary and pancreatic ducts by direct surgical intervention exists. Over a 10-yr period, 54 patients had postoperative bleeding from the stomach; 17 of these had had a resection of the stomach, 14 of which were of the exclusion type. Two case histories are presented. In one, a correct diagnosis was eventually made, but the patient died for lack of radical surgery to remove the bleeding ulcer. In the second case, correct diagnosis and radical surgery led to recovery. Because of the impossibility of direct x-ray and endoscopic examination, the diagnosis of bleeding, excluded ulcers is usually based on previous surgery for removal of a duodenal ulcer and the inability to confirm any other source of bleeding by x-ray. The author concludes that exclusion of the duodenal ulcer does not guarantee its cicatrization, that bleeding from ulcers remaining in the duodenum may recur, and that radical surgery is necessary to treat bleeding, excluded ulcers.

5672 THE EFFECT OF THE SIZE OF THE GASTRIC OUTLET ON GASTRIC EMPTYING AFTER VAGOTOMY FOR DUODENAL ULCER. (Eng.) George, W. D.; Cowley, D. J.; Royston, C. M.; Glass, H. I.; Spencer, J. (Univ. Hosp. South Manchester, Manchester, England). *Br. J. Surg.* 62(11):879-881; 1975.

To determine if pyloroplasty can reduce the size of the gastric outlet and lead to temporary retention of solids, gastric emptying of isotopically labeled solid meals was studied in 17 normal subjects and in 30 patients who had had an operation for chronic duodenal ulcer. Each patient had a vagotomy of the whole stomach, combined with either a Finney pyloroplasty to produce a large gastric outlet (16 patients) or a Heineke-Mikuliez pyloroplasty to produce a relatively small outlet (14 patients). At 10-22 days after operation, gastric emptying was equally and significantly slowed in both groups compared with the normal controls. This delay occurred regardless of whether the vagotomy was complete or incomplete. At 4-6 months after operation, emptying had returned to normal in the patients who had had a Finney pyloroplasty, but remained significantly slowed after Heineke-Mikuliez pyloroplasty. Mild symptoms of gastric stasis frequently occurred in both groups in the early postoperative period, but were rare 4-6 months after operation. There was no correlation between the incidence of these early symptoms of stasis and the size of the gastric outlet constructed. The construction of a large outlet pyloroplasty does not confer an advantage in gastric emptying over small outlet pyloroplasty.

5673 OPERATIVE MORTALITY AND POSTOPERATIVE MORBIDITY OF HIGHLY SELECTIVE VAGOTOMY. (Eng.) Johnston, D. (Bristol Royal Infirmary, Bristol, BS2 8HW, England). *Br. Med. J.* 4(5006): 545-547; 1975.

Because isolated case reports of highly selective vagotomies (HSVs) have described necrosis, peritonitis, and sometimes death as complications, a world-wide survey of the results of 5,539 HSVs performed electively for duodenal ulcer was carried out. The operative mortality was 0.3%. This was lower than that found in collected series after either vagotomy with drainage (0.8%) or gastric resection with or without vagotomy (>1%). Necrosis of the lesser curvature occurred in 10 patients (0.2%) after HSV and caused death in 5 (0.1%). This necrosis is probably ischemic in origin. Reperitonealization of the raw area on the lesser curvature and prompt laparotomy if the patient develops signs of peritonitis might lower the mortality still further. Three deaths were due to pulmonary embolism, one to mesenteric vascular occlusion, and four to myocardial infarction; such deaths might be reduced by the prophylactic use of low-dose heparin. Persisting gastric stasis requiring drainage occurred in only 0.1% of the patients in the early postoperative period and in 0.6% of the patients later; drainage procedures, which produce side effects such as early dumping, bilious vomiting, and diarrhea, could be abandoned if the mean incidence of recurrent ulceration after HSV remains close to its present level. HSV is probably the safest operation for duodenal ulcer because the alimentary tract is not opened and there is no anastomosis, suture line, or stoma.

SMALL INTESTINE

5704 RADIOGRAPHICAL AND ENDOSCOPICAL STUDIES ON TWO CASES OF INTRALUMINAL DIVERTICULUM OF THE DUODENUM. (Eng.) Wobser, E. C.; Koischwitz, D.; Kutz, K.; Loffler, A.; Miederer, S. E. (Med. Poliklinik der Universitat Bonn, Wilhelmstrasse 35-37, 5300 Bonn, W. Germany). *Endoscopy* 8(2):101-105; 1976.

Two cases of intraluminal diverticulum of the duodenum are reported with radiographic and endoscopic findings. A 40-yr-old man had a 2-yr history of epigastric distress following heavy meals; he had a history of nausea. Barium meal examination showed the typical radiographic features of the condition, a pouch beginning at the ampulla of Vater and lying completely within the duodenum. Endoscopy showed a pouch attached to the medial wall of the duodenum narrowing the lumen to about one-fifth of its original size. The second case, a 25-yr-old man, had a 12-month history of nausea and discomfort after heavy meals. Barium meal examination showed an intraluminal diverticulum with some degree of dilatation in the upper part of the duodenum. The ampulla of Vater could not be seen endoscopically, possibly because it was either within or covered by the pouch. Although the roentgenographic appearance is diagnostic, it is stressed that endoscopy can give further information about hemorrhage, inflammation, and localization of the ampulla of Vater.

5705 IMMUNOCHEMICAL STUDIES OF THE ENDOCRINE CELLS OF THE GASTROINTESTINAL TRACT. II. AN IMMUNOPEROXIDE TECHNIQUE FOR THE LOCALIZATION OF SECRETIN-CONTAINING CELLS IN HUMAN DUODENUM. (Eng.) Robinson, G.; Dawson, I. (Dept. Pathology, Univ. Nottingham, Nottingham, England). *J. Clin. Pathol.* 28(8):631-635; 1975.

The localization and characterization of secretin-containing cells in the human duodenum by the application of immunoperoxidase techniques to carbodiimide-fixed tissue are described. The techniques were applied to sections of duodenal mucosa obtained from two patients with pancreatic carcinoma. The carbodiimide-fixed tissue was embedded in polyethylene glycol. Staining of sections by both the direct and indirect techniques clearly demonstrated the presence of secretin-containing cells. Labeled cells were localized mainly in the epithelium lining the lower portions of villi and upper regions of the crypts. The cells were predominantly pyramidal in shape, and the same cell was often in contact with both the basal lamina and lumen. The reaction product for peroxidase label was always localized in the basal half of the cell. Sections that were stained by a modified, indirect immunoperoxidase procedure and processed for electron microscopy contained granules giving a peroxidase reaction, but ultrastructural preservation was so poor that it was impossible to determine which particular cells contained the reaction product. Although fluorescein-conjugated antisera give excellent results at the light microscopic level, the use of peroxidase-conjugated antisera may be preferable, because the end result is visible in the light microscope as a brown black deposit; histological counterstains can be applied; and the same sections are available for preparing electron microscopic ultrathin sections that will show antiserum localization, since the end product is electron dense. The successful development of immunochemical staining techniques based on peroxidase-conjugated antisera will now allow a more direct comparison between conventional hematoxylin and eosin preparations and immunochemically stained slides of the same specimen.

5706 FOLATE CONTENT OF IRANIAN BREADS AND THE EFFECT OF THEIR FIBER CONTENT ON THE INTESTINAL ABSORPTION OF FOLIC ACID.

(Eng.) Russel, R. M.; Ismail-Beigi, F.; Reinhold, J. G. (Veterans Admin. Hosp., 3900 Loch Raven Blvd., Baltimore, MD 21218). *Am. J. Clin. Nutr.* 29(7):799-802; 1976.

To explain the relatively low incidence of folate deficiency in central Iran, the folic acid content of various Iranian breads was determined, since bread is the staple food in Iran. In addition, the effect of the fiber content of the bread on the intestinal absorption of folic acid was studied. Tanok, the village wholemeal bread, had an average "free" folate content (without conjugase incubation) of 0.34 μg/g. Sangak and Bazari, leavened breads made from flours of high extraction rates and widely consumed in towns and cities, had free folate contents of 0.38 and 0.71 μg/g, resp. The folate content of these breads was significantly higher than that of white bread from refined flour (0.13 μg/g) or oatmeal bread (0.09 μg/g). Iranian breads also had a high content of indigestible fiber (1.6-4.2% of dry weight). Sequential folate absorption tests (tritiated pteroylmonoglutamic acid; PGA) were performed in four subjects using meals of increasing fiber content and fasting. No interference with folate absorption was found. Furthermore, *in vitro* studies did not demonstrate the formation of insoluble complexes between bread fiber and folic acid, which might indicate decreased availability. The average dietary intake of folate from Iranian breads is more than the daily requirement of PGA required to prevent anemia, and approaches that needed in pregnancy.

5707 PRIMARY UPPER SMALL-INTESTINAL LYMPHOMA. A REPORT OF 40 CASES FROM IRAN.

(Eng.) Nasr, K.; Haghighi, P.; Bakhshandeh, K.; Abadi, P.; Lahimgarzadeh, A. (Nemazee Hosp., Shiraz, Iran). *Am. J. Dig. Dis.* 21(4):313-323; 1976.

Forty cases of primary upper small intestinal lymphoma (PUSIL) in Iran are described. All patients were from a single province, and were selected from patients with pathologically proven lymphoma of the gastrointestinal tract and the upper small intestine. All subjects were Moslems, and with two exceptions, were from the rural and low socioeconomic brackets. The disease was predominantly noted in males under 30 yr of age. Special features of PUSIL included edema, steatorrhea, and an associated abnormal heavy chain protein. Clubbing was noted in eight patients. Of 34 subjects, 28 had serum albumin levels below 3 g/100 ml. The edema, which was found in nearly 20%, appeared to be related to a hypoalbuminemia due to protein loss in the gastrointestinal tract. The frequency of giardiasis was over twice that noted in a similar, but apparently normal, population. Anemia with a low reticulocyte count was a common finding. In 37 patients examined by barium meal, the results were abnormal and suggested a malabsorption pattern. There was evidence of narrowing and dilation, segmentation, puddling, and abnormalities of the mucosal pattern. There was consistent agreement as to the histologic type of lymphoma between peroral biopsy (21 patients) and laparotomy (small bowel, 25 patients or mesenteric nodes, 11). Reticulum cell sarcoma and lymphosarcoma accounted for 37 of the 40 cases. Although the etiology of PUSIL has not been determined, geographical distribution, exposure to environmental factors early in life, and low protein intake are specific features of the disease.

5708 PRIMARY DUODENAL TUMORS: A DIAGNOSTIC AND THERAPEUTIC DILEMMA.

(Eng.) Kibbey, W. E.; Sirinek, K. R.; Pace, W. G.; Thomford, N. R. (Ohio State Univ. Coll. Medicine, 410 W. Tenth Ave., Columbus, OH 43210). *Arch. Surg.* 111(4):377-380; 1976.

Because the diagnosis of duodenal tumors is difficult, the case records of 32 patients with duodenal neoplasms were reviewed, and the case history of the most recent patient, a 51-yr-old man, is presented. Five years prior to the discovery of a duodenal tumor, the patient experienced melena; upper gastrointestinal roentgenograms showed a small lesion on the duodenal bulb, interpreted as an ulcer. Because of recurrent symptoms (anemia, nausea, abdominal pain, and melena), two upper gastrointestinal series were carried out over the next few years; both were interpreted as normal. Fiberoptic endoscopy revealed a 1-cm ulcerated mass located 14 cm past the pylorus. At surgery, two masses were found in the third and fourth portions of the duodenum; these portions and 10 cm of the proximal jejunum were resected, and an end-to-end duodenojejunostomy was established. Both tumors were leiomyomas, and the patient made an uneventful recovery. Of the 32 cases, 10 had a total of 11 benign tumors, and 19 had malignant tumors. Three patients had small, functional Zollinger-Ellison tumors. The average age of patients with benign tumors was 53 yr, and that of patients with malignant tumors was 59 yr. Eight patients with benign tumors were symptomatic, and in all cases the symptoms were related to gastrointestinal bleeding. Of the patients with malignant tumors, exclusive of the periampullary carcinomas (4 patients), all had duodenal obstruction, hemorrhage, a combination of the two, or in a single case, jaundice from extensive liver metastases. All patients with periampullary lesions were jaundiced. Patients with the Zollinger-Ellison tumors had long histories of peptic ulcer disease and none had symptoms referable to a duodenal mass lesion. Of 17 patients with malignant lesions who had barium studies of the duodenum, tumors were visualized in only 9. Many patients had had symptoms for extended periods of time, and most of these had at least one previously unsuccessful attempt at diagnosis. Benign tumors were removed successfully from 9 of 10 patients. By the time of diagnosis, only 12 of 19 malignant lesions were resectable; of the 14 patients who underwent resection, only 2 survived over 5 yr. All patients with Zollinger-Ellison tumors underwent extensive gastric resection and tumor removal, and all survived over 5 yr. The diagnosis and treatment of duodenal tumors are often delayed because the symptoms resemble those of more common diseases. The authors suggest that a more aggressive diagnostic approach, including fiberoptic endoscopy, be undertaken, whenever a patient has symptoms possibly referable to the duodenum.

5709 THE PROBLEMS AND CLINICAL ASPECTS OF PRIMARY MALIGNANT NEOPLASMS OF THE SMALL INTESTINE. (Ger.) Spelsberg, F.; Schmidtler, F. (Chirurgische Klinik der Universitat, D-8000 Munchen 2, Nussbaumstrasse 20, W. Germany). *Munch. Med. Wochenschr.* 117(18):771-776; 1975.

Experience with 6,432 patients with malignant tumors of the digestive tract, seen over a 20-yr period, is reviewed. Only 42 of these cases (0.66%) involved the small intestine, including the duodenum, but excluding tumors of the ileocecal region, peripapillary duodenal carcinomas, metastatic small intestinal tumors, and mesenteric tumors. The ages of the patients ranged from 20 to 82 yr, averaging 56.3 yr; there were 22 men and 20 women. An average of 116 days elapsed between the first visit to a physician and surgery. The tumors occurring in the the small intestine included 21 carcinomas, 15 sarcomas, and 6 carcinoids. All of the small intestinal epitheliomas were adenocarcinomas. The sarcomas included 9 leiomyosarcomas, 2 lymphosarcomas, 1 spindle cell sarcoma, 1 fibrosarcoma, 1 reticulosarcoma, and 1 neurogenic sarcoma. The ileum was the site of the largest number of tumors (25 cases), followed by the jejunum (11 cases), and the duodenum (6 cases). The most common symptoms were abdominal pain (present in 83% of the patients), weight loss (67%), and intestinal hemorrhage (62%). Preferred surgical treatment was radical resection, including the lymphatics. Laparotomy revealed inoperable tumors in five cases. Only palliative surgery was possible in 24 cases, and satisfactory tumor removal was possible in only 13 cases. Metastases had been detected prior to surgery in 34 patients; the lymph nodes, liver, peritoneum, and lung were the most common sites. The early (8-54 days after operation) mortality rate was 19%; no patients have died immediately after surgery since 1970. The 3-yr survival rate was 20.5%, and the 1-yr survival rate was 36%. The overall 5-yr survival rate was 12.2%, and in the patients in whom radical surgery was possible, it was 66%.

5710 STRUCTURAL AND FUNCTIONAL CHANGES IN THE SMALL INTESTINE DURING THE COURSE OF DERMATITIS HERPETIFORMIS. (Ger.) Kryszewski, A.; Zoltowska, A.; Pawlik, H. (I Klinik des Instituts fur Innere Medizin, Med. Akademie, Gdansk, Poland). *Hautarzt* 26(3):133-136; 1975.

Structural and functional changes in the small intestine were examined in 13 patients with dermatitis herpetiformis. Total villous atrophy was seen in small intestinal capsule biopsies from two cases. Definite structural alterations were seen in five additional cases. Inflammatory infiltrations in the lamina propria were present in all of the 10 biopsies examined. Gastrointestinal symptoms were not reported by any of the patients, perhaps due to the focal nature of the changes in the intestinal mucous membrane. Normal xylose absorption and normal serum vitamin B12 levels were seen in most of the cases. Only one patient demonstrated impaired xylose absorption, and two had low serum vitamin B12 levels. No correlation was apparent between the intensity of mucosal alterations and the impairment of absorption in dermatitis herpetiformis. The similarities between the mucous membrane alterations in dermatitis herpetiformis and those seen in gluten enteropathy (celiac disease) suggest that a gluten-free diet should be tried in the treatment of dermatitis herpetiformis, and that strict dietary control is also necessary in evaluating other forms of therapy.

5711 DIAGNOSTIC AND THERAPEUTIC PROBLEMS RAISED BY TWO CASES OF EXUDATIVE ENTEROPATHY. (Fre.) Frexinos, J.; Rumeau, J.-L.; Fortas, L.; Douchez, J.; Ribet, A. (Hopital Purpan, 31052 Toulouse Cedex, France). *Sem. Hop. Paris* 51(3):177-184; 1975.

Exudative enteropathy syndromes present diagnostic and therapeutic difficulties due to their varied etiology. The cases of two men (aged 38 and 61 yr) are reported. The enteropathy was characterized by edema of the legs, accompanied by a hypoproteinemia and a notable lymphopenia with disturbances in the polyvinyl-pyrolidone-^{131}I test. Lymphography showed major anomalies, with blockage in one case, and slowed lymphatic drainage with signs of dysplasia in the other. In one case, surgery revealed a calcified lymph node, probably of tubercular origin. The etiology of both cases appeared related to anomalies of the lymphatic system. A low-fat diet and the intake of medium-chain triglycerides produced significant improvement.

5712 DIVERTICULAR DISEASE OF THE TERMINAL ILEUM.

(Eng.) Bloch, C.; Bryk, D. (30 E. 60th St., New York, NY 10022). *Mt. Sinai J. Med. N.Y.* 43(2):122-128; 1976.

Four cases of diverticular disease of the terminal ileum are summarized, and the case history of one of the patients is presented. Three patients had no symptoms originating from the lower right quadrant, and the diagnosis was noticed incidentally during a small bowel series. Two of these patients had coexistent diverticulosis of the ascending colon. The presented case, a 51-yr-old woman, had intermittent right lower quadrant pain. Radiographic examination showed numerous outpouchings along the medial wall of the terminal ileum. At surgery, an inflammatory mass in the mesentery of the ileum and ascending colon was found; this had been suggested by the radiographic findings. An ileocolic resection was performed. The more frequent routine use of pressure spot films of the right lower quadrant in small bowel studies has increased the number of cases of diverticular disease of the terminal ileum described in the recent literature.

5713 CONGENITAL DUODENAL DIAPHRAGMS IN ADULTS: A DELAYED CAUSE OF INTESTINAL OBSTRUCTION.

(Eng.) Cooperman, A. M.; Adachi, M.; Rankin, G. B.; Sivak, M. (Cleveland Clinic, 9500 Euclid Ave., Cleveland, OH 44106). *Ann. Surg.* 182(6):739-742; 1975.

Three cases in which congenital duodenal diaphragms caused intestinal obstruction in the adult are presented, and the recent literature is reviewed. Two of the patients were women, and the ages of the patients ranged from 59 to 73 yr. The symptoms included recurrent epigastric pain and fullness, nausea and vomiting, and weight loss. In all cases, the need for surgery was indicated by an upper gastrointestinal series, which revealed a massively dilated stomach, with no progression of barium beyond the duodenal bulb in the first patient, a 2-cm narrowed segment in the descending duodenum of the second patient, and delayed gastric emptying with evidence of significant retention in the third patient. In all patients, the duodenal diaphragms were discovered at surgery, and treatment consisted of duodenotomy, excision of the web, and transverse closure of the duodenum in one layer. At least 35 similar cases have been reported. Membranous obstruction accounts for only 0.8-25% of all small intestinal obstructions and 2% of duodenal obstructions. In 75% of cases, the diaphragm is located near the ampulla, and the opening is usually eccentric rather than central. The diagnosis is most often made by upper gastrointestinal series, which reveals a dilated duodenal bulb and stomach proximal to the web and without evidence of pyloric ulceration.

5714 MUCOSAL LESIONS IN THE HUMAN SMALL INTESTINE IN SHOCK.

(Eng.) Haglund, U.; Hulten, L.; Ahren, C.; Lundgren, O. (Sahlgren's Hosp., Goteborg, Sweden). *Gut* 16(12):979-984; 1975.

Hemorrhagic lesions occurring in the small intestinal mucosa of seven patients, who underwent surgery for different gastrointestinal disorders, were examined histologically and compared with lesions found in the small intestine of the cat during a standardized simulated shock. The case histories of the seven patients, who ranged in age from 25 to 86 yr, are presented. In four patients, there was no evidence of occlusive vascular disease in the mesenteric vessels, but they had been hypotensive for varying lengths of time. The other three patients showed signs of occlusive vascular disease in the intestine, but no general arterial hypotension, and the segments resected for histological examination were taken from the borders of macroscopically normal intestine. All patients exhibited similar lesions, which ranged from grade I (i.e., the development of subepithelial space at the tip of the villus) to grade V (i.e., disintegration of the lamina propria, hemorrhage, and ulceration in the mucosa). Identical changes in villous histology were seen during shock in the cat and in the patients. In both cases, the lesions were strictly confined to the mucosa. It is proposed that an extravascular short-circuiting of oxygen in the mucosal countercurrent exchanger and an intravascular aggregation of blood cells might produce tissue hypoxia, which makes the mucosa vulnerable to enzymatic degradation.

5715 ALTERATIONS IN BODY COMPOSITION FOLLOWING INTESTINAL OBESITY.

(Eng.) Spanier, A. H.; Kurtz, R. S.; Shibata, H. R.; MacLean, L. D.; Shizgal, H. M. (Royal Victoria Hosp., 687 Pine Ave. W., Montreal, Quebec H3A 1A1, Canada). *Surgery* 80(2):171-177; 1976.

The efficacy of jejunoileal bypass surgery for obesity was assessed by measurements of body composition in 20 patients. The measurements were performed by multiple isotope dilution before and at 3- to 6-month intervals following jejunoileal bypass. Prior to bypass, the excess body weight was due primarily to body fat (BF), which accounted for 52% of the total weight. The nonfatty component of body composition, the lean body mass, although slightly increased in size over controls, was essentially normal. Two distinct patterns were observed following bypass. In 12 patients followed for 8.4 ± 1.5 months, there was a 21% decrease in body weight, resulting entirely from a loss of BF. The total exchangeable potassium and intracellular water volume, both measurements of the body cell mass (BCM), were unchanged. In eight patients followed for 13.9 ± 2.1 months, the mean body weight decreased by 27% or 38.8 kg, due to a 26.6-kg reduction in BF and a 13.0-kg decrease in the BCM. This was accompanied by a relative expansion of the extracellular mass. As a result, the mean Na_e/K_e ratio increased significantly ($p<0.05$) from a normal prebypass value of 0.95 ± 0.7 to 1.46 ± 0.11 following bypass. In 8 of the 20 patients, there was an undesirable loss of BCM with a relative expansion of extracellular supporting component of body composition, a pattern characteristic of malnutrition.

SMALL INTESTINE

Malabsorption

5741 REVERSIBLE ENTERITIS AND LYMPHOPENIA IN INFANTILE X-LINKED AGAMMAGLOBULINEMIA. (Eng.) Rhee, J. W.; Gryboski, J. D.; Sheahan, D. G.; Dolan, T. F., Jr.; Dwyer, J. M. (Yale Univ. Sch. Medicine, 333 Cedar St., New Haven, CT 06510). *Am. J. Dig. Dis.* 20(11):1071-1075; 1975.

The case of a child with infantile X-linked agammaglobulinemia, who had severe diarrhea associated with intestinal villous atrophy and intramucosal bacteria without evidence of giardiasis or lactase deficiency, is presented. A diagnosis of X-linked agammaglobulinemia was made when the patient was 7 months old; monthly gamma globulin injections maintained his serum immunoglobulin G level between 200 and 270 mg%; it had previously been 43 mg%. At 17 months of age, the patient developed diarrhea, vomiting, and fever. A primary bacterial etiology of the diarrhea was supported by the presence of total villous atrophy and crypt elongation in the small bowel, the presence of mucosal inflammation with demonstrable intramucosal bacilli, and the absence of protozoal or parasitic infestation. On 12 attempts, a virus was never isolated from the stool, urine, cerebrospinal fluid, or nasopharyngeal washings. The presence of *Candida albicans* in the child's stool suggested a superimposed fungal infection, but the diarrhea continued after nystatin therapy. Responses to p.o. metronidazole, cholestyramine resin, or intrajejunal infusion of gamma globulin were also absent. Extreme peripheral lymphopenia was observed, with absolute lymphocyte counts ranging from 71 to 535/mm^3; differential lymphocyte analysis on three occasions revealed 11, 9, and 3% to be thymus-derived (T lymphocytes) and no detectable bone marrow-derived (B) lymphocytes. The child's lymphocyte count slowly returned to normal, as did the percentage of T lymphocytes (58%), following ampicillin therapy (250 mg, 4 times/day); clinical improvement was rapid, and the diarrhea was reduced within a week. This case illustrates the fact that a reverisbile enteritis in infantile X-linked agammaglobulinemia may be associated with factors other than giardia and intestinal mucosal enzyme deficiency. The enteritis responded most directly to antibiotic therapy, and bacterial enteritis should be considered in such patients showing poor response to other therapy.

5742 THE STRUCTURE AND FUNCTION OF THE SMALL INTESTINE IN DERMATITIS HERPETIFORMIS. (Pol.) Kryszewski, A. (I Clinic, Inst. Internal Diseases, Medical Acad., Gdansk, Poland). *Przegl. Dermatol.* 61(6):875-882; 1974.

Data suggesting similarities in the structure and function of the small intestine in dermatitis herpetiformis (DH) and in the malabsorption syndrome (gluten enteropathy) are reviewed. Experiments during the years 1966-1974 showed that the structural changes in the mucous membrane of the small intestine in DH, manifested by the dwindling of intestinal villi, are indistinguishable from the changes seen in the malabsorption syndrome. No such similarity has been observed for the function of the small intestine in the two diseases. The characteristic symptoms of the malabsorption syndrome (diarrhea; defective absorption of folic acid, xylose, glucose, and vitamin B_{12}; low levels of serum carotenes and immunoglobulin M; and splenic atrophy) do not always occur in DH. The most common symptom of DH shared by the malabsorption symdrome is poor folic acid absorption; the least common symptom is poor absorption of xylose, which is usually normal in DH patients, even if the mucous membrane of the small intestine shows profound morphological changes. A gluten-free diet in patients with DH or the malabsorption syndrome shows conflicting results, although the most recent studies indicate that the diet's effectiveness depends on its duration. Treatment with a gluten-free diet for an adequate length of time seems to be useful in the management of DH.

5743 BONE DEMINERALIZATION IN LACTOSE INTOLERANCE. (Fre.) Lebarbier, P.; Arlet, P.; Latorzeff, S.; Arlet, J. (Hotel-Dieu, 3152 Toulouse Cedex, France). *Rev. Med. Toulouse* 11(3):205-215; 1975.

Two cases (61-yr-old man and a 65-yr-old woman) of osteomalacia with a lactose intolerance are reported. In the first case, there was general demineralization with vertebral and pelvic fractures; calciuria was low (44, 34 mg/day) and alkaline phosphatases were high (92 IU). Urinary excretion of calcium was 50% of the injected dose. This patient had spontaneously eliminated milk and butter from her diet since the age of 13 because they provoked nausea and diarrhea. In the second case, there was also demineralization; alkaline phosphatases were 93 IU. calcemia 84-89 mg, and calciuria 50-100 mg. Iliac bone biopsy confirmed severe osteopenia with secondary malacia. The patient had been suffering from polyarthritis for 30 yr and had been receiving cortisone treatment for 6 yr. The patient's lactose intolerance may have contributed to the calcium malabsorption caused by the cortisone and thus have favored the development of the osteomalacia. Lactose intolerance seems to be an additional factor in decalcification (idiopathic osteoporosis and low calciuria osteomalacia). Its mechanism of action may be indirect (calcium deficit), direct (lactose deficiency), or lactose may only favor calcium absorption if both calcium and lactose are simultaneously present in the intestine.

5744 INTOLERANCE TO COW MILK PROTEINS IN CHILDREN. REVIEW OF 30 CASES. (Fre.) Deleze, G.; Nussle, D. (Institut de pharmacologie clinique de l'Universite de Berne, Murtenstrasse 35, CH-3010 Berne, Switzerland). *Helv. Paediatr. Acta.* 30(2): 135-149; 1975.

Thirty patients with intolerance to cow milk proteins were studied retrospectively, and 22/30 were followed for 3-14.5 yr. Intolerance usually begins in the first six months of life following a brief exposure to the proteins, but may appear later, especially after an intestinal infection. Symptomatology is predominantly digestive, frequently accompanied by respiratory, cutaneous, and general symptoms. In almost 50% of cases, there are signs of exudative enteropathy or generalized malabsorption with lesions of the jejunal mucosa. Protein intolerance must also be differentiated from lactose intolerance. The immediate evolution of protein intolerance is sometimes complicated by other alimentary intolerances, either immunological or secondary to lesions of the jejunal mucosa. There are three types of protein intolerance: acute anaphylactic (20%), chronic benign (43%, colitis), and severe chronic with intestinal malabsorption (37%), which is sometimes difficult to differentiate from celiac disease. Most often, the protein intolerance is transitory, disappearing between 2-2.5 yr of age. Long-term prognosis is good, as subsequent weight gain and height growth are normal, and rarely, is there residual allergic or digestive pathology.

LARGE INTESTINE

5760 PROPHYLACTIC ORAL ANTIMICROBIAL AGENTS IN ELECTIVE COLONIC SURGERY: A CONTROLLED TRIAL. (Eng.) Goldring, J.; McNaught, W.; Scott, A.; Gillespie, G. (Victoria Infirmary, Glasgow S2, Scotland). *Lancet* 2(7943):997-1000; 1975.

The efficacy of prophylactic p.o. metronidazole specifically directed against anaerobic colonic microflora in combination with kanamycin to reduce the aerobic flora was evaluated in 50 patients undergoing elective colonic surgery. The patients received 200 mg of metronidazole and 1 g of kanamycin every 6 hr for 3 days before surgery, while 50 age- and sex-matched controls received dietary and mechanical preparation alone. The number of both aerobic (coliforms) and anaerobic (*Bacteroides*) microflora was significantly reduced in the treated patients (6 coliforms and 2 *Bacteroides*) in comparison to the controls (23 coliforms and 20 *Bacteroides*). There was a significant reduction in postoperative wound infection; 11 of 25 controls and only 2 of 25 treated patients developed a postoperative wound infection. Only three patients and all controls required systemic antibiotics in the first week after surgery. One control patient died from *Bacteroides* septicemia. No toxic or other side effects from this prophylactic regimen occurred during the study. This treatment seems valuable in suppressing both aerobic and anaerobic colonic microflora in patients undergoing colonic surgery.

5761 AGANGLIONOSIS OF THE ENTIRE BOWEL.

(Eng.) Talwalker, V. C. (J. J. Hosp., 394 Lamington Road, Bombay 400 004, India). *J. Pediatr. Surg.* 11(2):213-216; 1976.

The case reports of three infants with aganglionosis of the entire bowel (AEB), from a group of 50 infants with Hirschsprung's disease, are presented, and the literature concerning AEB is briefly reviewed. The first patient, a 4-day-old boy, had bile-stained vomitus and abdominal distension, but had passed meconium. At laparotomy, there was gross dilation of the jejunum for about 25 cm, starting 20 cm from the duodeno-jejunal flexure. Just proximal to the ileo-cecal junction, there was another segment of dilated intestine that was cyanic and showed a tear in the serosal surface and mesentery. This loop was resected, and an end-to-end anastomosis was performed. Histological examination of the biopsy specimens revealed no ganglion cells in the rectum, ileum, or jejunum. A few large cells with abundant cytoplasm suggestive of degenerating ganglion cells were noted. The rectum and ileum contained myenteric plexus nerve fiber, while in the jejunum, only sheath cells were observed in the myenteric plexus. In the other patients, a 36-hr-old boy and a 4-day-old boy, no meconium was passed. The obstruction in both cases was in the ileum, 30 or 40 cm from the ileo-cecal valve. Ganglion cells were absent from the duodeno-jejunal flexure to the rectum in both cases. In one patient, the meconium in the intestine was noted to be easily washed away (unlike meconium in meconium ileus), and the distal head of the meconium column was the same color as the rest of the column. All the infants died. AEB should be suspected in a neonate with intestinal obstruction if the obstruction is found at laparotomy to be at the level of the ileo-cecal region and there is no obvious discontinuity of the bowel.

5762 ASPECTS OF APPENDICEAL ABSCESS IN CHILDREN WITH SPECIAL REFERENCE TO DELAYED APPENDECTOMY.

(Eng.) Gierup, J.; Karpe, B. (Karolinska sjukhuset, Stockholm, Sweden). *Acta Chir. Scand.* 141(8):801-803; 1975.

To determine the value of delayed appendectomy following conservative management of appendiceal abscess, the risk of recurrence, the frequency of postoperative complications, and the risk of overlooking malignant disease were studied in 52 children. The treatment regime in all cases was conservative treatment initially (bed rest, broad spectrum antibiotics, and parenteral fluids when necessary), followed by delayed elective appendectomy. Ten patients had a recurrence a mean of 8 weeks after the initial attack, but before the appendectomy was performed. The appendix was immediately removed in seven of these patients, delayed appendectomy was performed in two, and in one, the appendix was left behind after draining the abscess. In the 37 patients without clinical recurrence, delayed appendectomy was performed after a mean of 9.5 weeks. In two patients, potentially malignant conditions were discovered at appendectomy. There were no significant postoperative complications. The results indicate that it is essential to perform delayed appendectomy in children with appendiceal abscess. This procedure is recommended after an interval of 4-6 weeks.

5763 INTUSSUSCEPTION OF THE APPENDIX IN CHILDREN.

(Eng.) Atkinson, G. O.; Gay, B. B., Jr.; Naffis, D. (Emory Univ. Sch. Medicine, Atlanta, GA 30322). *Am. J. Roentgenol.* 126(6):1164-1168; 1976.

Two pediatric cases of intussusception of the appendix are reported. Symptoms included cramping pain, vomiting, and diarrhea or constipation, but no blood in the stools. In the first patient, a 2.5-yr-old girl, a barium enema examination revealed an intussusception that could not be reduced. On repeat barium examination, ileocolic intussusception was reduced to the cecum where there was free reflux of barium into the terminal ileum. A lobular filling defect persisted in the base of the cecum, and no appendiceal filling was seen. At surgery, the mesoappendix was divided and ligated. After further inverting the base of the appendix into the cecum, the base was closed by encircling sutures. In the second patient, a 4.5-yr-old girl, abdominal roentgenograms revealed a soft tissue mass, suggesting an intussusception. At surgery, a partially inverted appendix was found, with several enlarged lymph nodes showing benign inflammatory change. A right hemicolectomy was performed with an end-to-end anastomosis between the distal ileum and ascending colon. A Meckel's diverticulum was also found and removed. Pathologically, there was focal ulceration and acute inflammation of the inverted appendiceal surface, lymphoid hyperplasia, and subacute inflammatory changes.

5764 THE CATHARTIC COLON: PATHOLOGICAL FINDINGS AND RADIOLOGICAL/PATHOLOGICAL CORRELATION.

(Eng.) Urso, F. P.; Urso, M. J.; Lee, C. H. (Akron City Hosp., Akron, OH). *Radiology* 116(3):557-560; 1975.

The case of a 42-yr-old woman with a cathartic colon is presented. The patient presented with recurrent urinary tract infection and occasional blood-streaked stools. A barium enema examination revealed reflux into the terminal ileum, a shortened colon, lack of haustra, an abnormal terminal ileum and colonic mucosa, and a 5-cm filling defect in the sigmoid, all suggesting long-standing ulcerative colitis and carcinoma. Sigmoidoscopy revealed edema and punctate ulcerations. At laparotomy, the small bowel was normal, except for a dilated and atonic distal ileum. The colon was dilated, atonic, and foreshortened. A subtotal colectomy was performed, and only 20 cm of ileum and 45 cm of colon were removed. Histologically, there was severe mucosal atrophy, suggesting that ulcerative colitis was unlikely. A single layer of tall columnar epithelial cells replaced the normal glandular pattern in some areas.

Exuberant crypt abscesses, seen in active ulcerative colitis, were absent. The mucosa and lamina propria were infiltrated by mononuclear cells. The distribution of the disease process in the resected colon and the absence of characteristic features of chronic ulcerative colitis led to a detailed medical history. The patient had constipation rather than diarrhea, and had an 18-yr history of habitual laxative use; she admitted taking two tablets of bisacodyl daily for 4 yr. Plain abdominal films taken 6 yr earlier revealed a dilated, air-filled cecum and loss of haustral markings. Unexplained hypokalemia and hypoalbuminemia had been noted on previous admissions; the authors believe that the albumin loss occurred through the colonic mucosa. Extreme mucosal atrophy should alert the pathologist to possible laxative abuse.

5765 PSEUDOMEMBRANOUS COLITIS TREATED WITH COMPLETELY DIVERTING ILEOSTOMY. (Eng.)

Saylor, J. L.; Andersen, C. B.; Tedesco, F. J. (Washington Univ. Sch. Medicine, 4960 Audubon Ave., St. Louis, MO 63110). *Arch. Surg.* 111(5):596-598; 1976.

The case of a 43-yr-old man in whom a completely diverting ileostomy was performed adjunct to the treatment for life-threatening pseudomembranous colitis is reported. The patient had been treated for 10 months for hypertension and progressive chronic renal failure secondary to glomerulosclerosis. He presented with diarrhea, hemoptysis, bilateral lobar pneumonia, and azotemia. He was treated with ampicillin for 10 days, receiving a total of 18.5 g. A biopsy specimen taken at sigmoidoscopy confirmed the diagnosis of pseudomembranous colitis. Despite treatment (hemodialysis every 48 hr, fluid and electrolyte therapy with central venous pressure monitoring, and vigorous albumin replacement), the patient's clinical condition deteriorated, with increasing ascites and generalized seizures. A completely diverting ileostomy was performed by transecting the ileum 12 cm from the ileocecal valve and oversewing the distal stump. On the first postoperative day, total parenteral hyperalimentation and daily hemodialysis were begun. By the second postoperative day, the severe diarrhea had dramatically stopped, and by the sixth postoperative day, albumin therapy was discontinued. Oral feeding was begun on the 14th day. Sigmoidoscopy on the 20th postoperative day showed resolution of the colitis. Three months later, sigmoidoscopy and a barium enema examination gave normal results. The ileostomy was closed, and continuity was reestablished with an end-to-end anastomosis. Both the mode of therapy and the coincident disease processes make this case particularly interesting. Early diverting ileostomy can be an important adjunct to the therapy of unusually severe cases of pseudomembranous colitis.

5766 PSEUDO-OBSTRUCTION OF THE COLON. (Eng.)

Spira, I. A.; Rodrigues, R.; Wolff, W. I. (Beth Israel Medical Center, 10 Nathan D. Perlman Pl., New York, NY 10003). *Am. J. Gastroenterol.* 65(5):397-408; 1976.

The literature on pseudo-obstruction of the colon is briefly reviewed, etiological factors are analyzed, and eight characteristic case histories are presented. The 212 cases reported in the literature were divided into 13 groups on the basis of suspected etiology. Of the total, 35% followed normal pregnancy or cesarian section. When other pelvic surgery and pelvic traumata were included, the figure approached 43%. Idiopathic cases accounted for 22%; intra-abdominal inflammation, 13%; cardiac failure and myocardial infarction, 8%; and retroperitoneal disease, 7%. Alcoholism has been reported as an important factor. It is postulated that pregnancy or uterine surgery interferes with parasympathetic outflow from sacral segments S2, S3, and S4, and disrupts the neurostimulatory balance between proximal (vagus-supplied) and distal colon and between parasympathetic and sympathetic nerve supplies to the distal colon. A functional obstruction would occur where proximal and distal nerve supplies overlap. Cardiac failure and myocardial infarction can cause vagal inhibition, resulting in a similar situation. Intra-abdominal inflammation, uremia, and lead poisoning may also in some way interfere with the sympathetic-parasympathetic balance or homeostasis of the proximal and distal parasympathetic supply. Early diagnosis is stressed. Emergency water-soluble contrast enemas should be instituted. Close monitoring of the patient's vital signs and regular examination of the abdomen are essential. Electrolyte balance should be checked regularly, and radiological evaluation should be performed to determine the degree of colonic distention. Treatment is usually decompression by a tube cecostomy. In cases of gangrene or extensive splitting of the *Taenia coli*, resection may be necessary. Barium enema and colonoscopy should be performed prior to discharge. The condition typically does not recur.

5767 COLONOSCOPIC PERFORATION: ITS EMERGENCY TREATMENT. (Eng.)

Jacobsohn, W. Z.; Levy, A. (Shaare-Zedek Hosp., 161 Jaffa St., P.O. Box 293, Jerusalem, 91-000, Israel). *Endoscopy* 8(1):15-17; 1976.

The case of a 60-yr-old woman in whom colonic perforation occurred during diagnostic colonoscopy is presented, and emergency treatment of this complication is described. The perforation occurred in an area of adhesions secondary to pelvic surgery. Immediately after the perforation, the patient entered into vascular collapse and respiratory distress, and the abdomen was distended. The introduction of a large bore i.v. catheter into the abdominal cavity with the release of the pneumoperitoneum resulted in an immediate return of vital signs. The patient subsequently underwent surgery and recovered. It is felt that this method of emergency treatment can be life-saving in a patient in whom perforation occurs during colonoscopy.

5768 COLONIC POLYPOID DISEASE: NEED FOR TOTAL COLONOSCOPY. (Eng.) Coller, J. A.; Corman, M. L.; Veidenheimer, M. C. (Lahey Clinic Foundation, 605 Commonwealth Ave., Boston, MA 02215). *Am. J. Surg.* 131(4):490-494; 1976.

The need for endoscopic evaluation of radiographically suspected benign colonic polyps was evaluated, and the need to examine the entire colon when a colonic polyp is encountered was studied. Colonoscopic examination of the entire colon was performed on 146 patients for radiographically suspected benign polypoid disease. Of 36 patients who did not have a neoplastic lesion at the suspected site, 7 had unsuspected small benign polypoid adenomas elsewhere in the colon. Of the remaining 110 patients, all of whom had a neoplastic lesion at the radiographically suspected site, 17 lesions were either adenocarcinomas or neoplastic polyps with invasive carcinoma. In 62 of the 110 patients, 128 additional unsuspected neoplastic polyps were found. Six of the additional neoplastic lesions were either adenocarcinomas or polyps with invasive carcinoma, and four of these malignant lesions were in patients who had a benign polyp at the radiographically suspected site. Suspected colonic polypoid disease should be evaluated colonoscopically, despite radiographic evidence of benignity. Colonoscopic evaluation in colonic polypoid disease should include examination of the entire colon with pathologic documentation of all polypoid lesions encountered.

5769 FIBRIN THROMBI, A CAUSE OF CLINDAMYCIN-ASSOCIATED COLITIS? (Eng.) Bogomoletz, W. V. (Queen Mary's Hosp., London, England). *Gut* 17(6):483-487; 1976.

Because fibrin thrombi have been previously found in necropsy material that included cases of ischemic and pseudomembranous enterocolitis, studies were carried out to verify the presence of fibrin thrombi in rectal biopsies of five patients with clindamycin-associated colitis. The clinical data of each patient are summarized; the bowel symptoms improved in all patients after the withdrawal of clindamycin. Fibrin microthrombi were identified in capillaries from all five patients. In the three biopsies that showed pseudomembranous colitis, fibrin thrombi were seen at random in capillaries lying directly below the pseudomembranes and in capillaries situated in the deeper and adjacent portions of the mucosa. In the two specimens showing nonspecific colitis (without pseudomembranes and without mucosal necrosis), fibrin thrombi were found only in the superficial capillaries. Many other capillaries showed only severe congestion. The identification of capillary thrombi with Lendrum MSB was more effective than with sections stained with hematoxylin-eosin. These findings indicate that fibrin thrombi in capillaries are probably more common in rectal biopsies from cases of clindamycin-associated colitis than would appear from the literature. It is possible that capillary thrombosis is the initial cause of the colitis, and that clindamycin has only, if any, a secondary effect on an already damaged and ischemic mucosa.

LARGE INTESTINE

Ulcerative Colitis

5817 BISEPTOL IN THE TREATMENT OF ULCERATIVE COLITIS. (Pol.) Tkaczewski, W.; Niedzielska, H. (Clinic Infectious Diseases, WAM, Lodz, Poland). *Pol. Tyg. Lek.* 30(7):293-294; 1975.

The efficacy of biseptol, a compound of trimethoprim and sulfamethoxazole, in the treatment of ulcerative colitis was tested in 20 patients with clinically confirmed disease. Twelve patients had recurring disease. At the beginning of treatment, the dosage was 2 tablets twice a day; upon visible improvement, the dosage was reduced to 2 tablets once a day. The patients' progress was followed up by routine daily clinical examination (temperature measurements, stool exam, and check-up for abdominal pains), supplemented by weekly proctoscopic examination and morphological and blood tests (blood count, level and composition of blood proteins, activity of alanine aminotransferase). At the end of treatment (2 weeks to over 2 months), seven cases showed good results: a drop in temperature, disappearance of abdominal pains and of diarrhea, and a decrease in the production of pus from the mucosa of the large intestine. Ten cases showed satisfactory results; the ulceration of the large intestine persisted. Three cases showed no improvement at all. The results confirm the suitability of biseptol for the treatment of ulcerative colitis.

5818 ACETYLATION POLYMORPHISM OF SULFAPYRIDINE IN PATIENTS WITH ULCERATIVE COLITIS AND CROHN'S DISEASE. (Eng.) Das, K. M.; Eastwood, M. A. (Albert Einstein Coll. Medicine, 1300 Morris Park Ave., Bronx, NY 10461). *Clin. Pharmacol. Ther.* 18(1):514-520; 1975.

The consistency of acetylator phenotyping was studied on the basis of sulfapyridine (SP) metabolites obtained from sulfasalizine (SASP) in 122 patients with ulcerative colitis and Crohn's disease. The patients were divided into four groups. Group A consisted of 21 patients (16 ulcerative colitis, 5 Crohn's disease) with new, untreated disease. Within 24 hr of admission, these patients were classified as either fast or slow acetylators by the administration of sulfadimidine. Treatment with SASP, steroids, and other standard therapies followed. Group B was composed of nine patients (6 ulcerative colitis, 3 Crohn's disease), who were admitted with relapse or who were receiving SASP before hospitalization. Treatment was similar to that used for Group A. Group C consisted of 31 patients, (20 ulcerative colitis, 11 Crohn's disease) in remission or experiencing only mild disease. They had been using SASP for 6 months to 15 yr. Group D consisted of 44 patients with ulcerative colitis and 27 with Crohn's disease who had been taking SASP. Blood samples taken from this group to estimate SASP metabolites; they provided an estimate for the frequency of acetylator phenotypes in this population. Blood and urine were collected from all patients. Results indicated that SP shares the same acetylation polymorphism as sulfadimidine. All patients phenotyped as fast or slow acetylators by the sulfadimidine method belonged to the same class with SP. Among patients with ulcerative colitis and Crohn's disease, the mean serum and urine t^2 values did not differ significantly between slow (serum=26.0 ± 8.0%; urine=40.6 ± 9.7%) and fast (serum=63.3 ± 9.2%; urine=75.7 ± 8.2%) acetylators. With an altered dose of SASP (2-8 g/day), the total SP concentration changed proportionally (10-80 μg/ml serum), while the acetylation observed remained constant. It is concluded that a single study of serum can determine acetylator phenotype in patients on sulfasalazine therapy without any other drug and may help ascertain dosage and assess side effects.

5819 SERUM C_3 and C_4 COMPLEMENT COMPONENTS IN ULCERATIVE COLITIS AND CROHN'S DISEASE. (Eng.) Ward, M.; Eastwood, M. A. (Western General Hosp., Univ. Edinburgh, Edinburgh EH4 2XU, Scotland). *Digestion* 13(1/2):100-103; 1975.

Because of the suggestion that local formation of cytotoxic complement-binding immune complexes contributes to tissue destruction in inflammatory bowel disease, serum C_3 and C_4 components were estimated by radial immunodiffusion in 32 patients with Crohn's disease, 30 patients with ulcerative colitis, 13 asymptomatic patients who had undergone total colectomy for ulcerative colitis, and 14 healthy controls. The mean serum C_3 and C_4 concentrations were increased compared to controls (86.3 and 25.3, resp.) in patients with Crohn's disease (98.9 and 38.8, resp.) and in patients with ileostomy (106.8 and 42.3, resp.), but was only statistically significant for C_4 ($p<0.01$ for both groups). The elevated C_4 concentration in the subjects with ileostomy may be related to the known persistence of disturbances of immunoglobulin metabolism in ileostomy patients, or to the fact that patients with severe and extensive ulcerative colitis are more prone to surgery. The mean C_3 concentration in patients with ulcerative colitis in remission (69.4) was significantly lower than in controls ($p<0.05$). In patients with Crohn's disease in remission, the C_3 and C_4 levels (109.5 and 43.5, resp.) were increased in comparison with controls. The difference between the two diseases in remission may be partly due to difficulties in the clinical determination of true remission of Crohn's disease or may reflect fundamental differences in the repair process in the two conditions. Increasing activity in ulcerative colitis was associated with increasing concentrations of C_3 and C_4. The mean concentration of C_3 in those patients with ulcerative colitis involving the entire colon (109.7) was significantly higher than that in patients with distal disease (79.6, $p<0.05$). These results support previously published reports of minor elevations or normal levels in total complement in ulcerative colitis.

PANCREAS

Pancreatitis

5836 SURGICAL TREATMENT OF CYSTS AND FISTULAS OF THE PANCREAS. (Rus.) Borovyi, E. M.; Nesterenko, L. N.; Bas, V. M.; Syvyi, N. Yu. (Dept. Surgery Digestive Tract, 50th Anniversary of USSR Rovno Provincial Hosp., Rovno, USSR). *Klin. Khir.* (5):26-30; 1975.

Experience with surgical treatment of 32 cases of pancreatic cysts is reviewed. Four patients were children under 10 yr, two patients were between 11 and 20 yr, nine patients were aged 21-30, seven patients were 31-40, six patients were 41-50, and four patients were over 60 yr. Cyst formation was caused by acute pancreatitis in 22 cases and by trauma in 10 cases. The location of the cysts was determined by roentgenological examination in 23 of 29 patients; 3 were in the head of the pancreas, 15 in the body of the gland, and 5 in its tail. Preoperative complications included rupture of the cyst and development of peritonitis (3 cases), infection of the cyst (4 cases), and bleeding (1 case). In addition, 13 patients developed mechanical jaundice, and 3 developed obstruction of the duodenum. The type of surgery was selected according to general condition of the patient and the surgical risk. Marsupialization of the cyst was performed in 14 cases, resection of the cyst in 2 cases, cystoenteroanastomosis by Shalimov's modification in 13 cases, cystojejunoduodenoplasty after Karavanov in 2 cases, and lumbobotomy and draining of the cyst in 1 case. No deaths occurred immediately after surgery. Two patients died 6 months later, one from diabetes and one from hepatargia after bile duct surgery. Five patients developed pancreatic fistulas that, despite conservative therapy, persisted 6-12 months after the operation. In these cases, Littman's modified surgical method was applied, implanting the fistula track and fistula into the jejunum, creating a dead end after Shalimov and Braun's anastomosis. The immediate and long-term results are satisfactory.

5837 PANCREATITIS AFTER CARDIAC SURGERY: A MORPHOLOGIC STUDY. (Eng.) Feiner, H. (Univ. Hosp., 550 First Ave., New York, NY 10016). *Am. J. Surg.* 131(6):684-688; 1976.

The incidence of pancreatitis was determined in 182 patients who died after cardiac surgery, and the pathogenesis of pancreatitis complicating this surgery was defined. Thirty-four instances of pancreatitis were recorded, but in five of these, pancreatitis was possibly related to events other than cardiac surgery. In the remaining 29 patients, pancreatitis was graded as mild (scattered focal parenchymal necrosis and fat necrosis, 17 patients), moderate (same changes, but quantitatively increased, 8 patients), or severe (confluent zones of pancreatic necrosis, 4 patients). In all instances, there was evidence of parenchymal necrosis with or without fat necrosis. In some patients, necrosis affected the periphery of lobules with preservation of the centers. Necrosis was usually associated with a sparse leukocytic infiltrate. Microscopic evidence of thromboembolism was noted in nine patients. The vessel types in which thromboemboli were found were muscular artery (1 patient), small artery (1), arteriole (5), capillary (1), venule (3), and vein (1). Since only one or two sections of each gland were available for histologic evaluation, the true incidence of pancreatic thromboemboli is probably greater than that actually recorded. Pancreatitis was not related to any particular surgical procedure. Because both arterial thromboemboli and venous thrombosis occurred, and these processes affected vessels of various caliber, a variety of factors must predispose to the formation of these thrombi. The findings indicate that pancreatitis occurring after cardiac surgery is ischemic in nature. The ischemia may be due to mechanical obstruction of blood vessels secondary to a variety of causes, or it may be functional, i.e., due to hypoperfusion. The assessment of hemodynamic status and coagulation profile in conjunction with serum levels of pancreatic enzymes may aid in the early recognition and management of this complication.

5838 A CONTROLLED CLINICAL TRIAL OF TRASYLOL IN THE TREATMENT OF ACUTE PANCREATITIS. (Ger.) Trapnell, J. E.; Rigby, C. C.; Talbot, C. H.; Duncan, E. H. L. (Royal Victoria Hosp., Bournemouth, England). *Med. Welt* 25(50):2106-2111; 1974.

A double-blind study to examine the effectiveness of aprotinin in the treatment of acute pancreatitis was carried out. Treatment in all cases was begun immediately upon establishment of a confirmed or suspected diagnosis, and consisted of analgesics, fluid replacement, cristamycin, propantheline bromide, and aprotinin A or B. The 53 patients treated with aprotinin A were similar to the 52 treated with aprotinin B, with respect to age, severity of initial illness, and time between appearance of symptoms and drug administration. A significant difference in overall mortality was seen between the two groups: 4 patients died in group A, and 13 in group B. After these findings were obtained, it was found that group A had been given active aprotinin, and group B, a placebo. Increased mortality was seen with increasing age in group B. The initial assessment of the severity of the pancreatitis was only partially correlated with the course of the illness. The number of patients in whom the disease course was evaluated as mild was greater in group A than in group B (57% versus 22%), and the number of cases evaluated as severe was greater in group B (15%, compared to 11% for group A). Only an overall consideration of the course allowed satisfactory evaluation, since any single symptom could vary, regardless of treatment. Administration of aprotinin in all cases of acute pancreatitis seems indicated.

5839 SPHINCTEROPLASTY IN SELECTED CASES OF ACUTE RECURRENT PANCREATITIS. (Eng.) Hutson, D. G.; Zeppa, R.; Levi, J. U. (Univ. Miami Sch. Medicine, P.O. Box 520875, Biscayne Annex, Miami, FL 33152). *Am. Surg.* 42(3):163-165; 1976.

The case histories of two patients who were successfully treated with sphincteroplasty for acute, recurrent pancreatitis are presented. The patients, two male alcoholics (aged 35 and 45 yr), repeatedly experienced abdominal pain and hyperamylasemia when attempts at p.o. feeding were made. Both patients differed from previously reported cases of acute pancreatitis in that surgical exploration and pancreatography failed to demonstrate obstructive lesions of the pancreatic or common bile ducts. At surgery, an inflamed pancreas, with marked edema in the entire pancreatic and peripancreatic area, was seen in the first patient, together with retroperitoneal fat necrosis in the lower quadrant. A similar picture was seen in the second patient, and a pancreatogram revealed evidence consistent with acute pancreatitis, but without ductal dilatation or local obstruction. Sphincteroplasty in both patients was followed by an uncomplicated recovery. A 10-month follow-up examination in the second patient revealed that he was asymptomatic and had maintained his weight. Because of the risks involved in this operation, it should be limited to uncommon situations, as in these patients.

5840 MECHANISMS OF HYPOCALCEMIA IN ACUTE HEMORRHAGIC PANCREATITIS. (Eng.) Peoples, J. B.; Webster, M. W., Jr.; Carey, L. C. (Univ. Pittsburgh Sch. Medicine, Pittsburgh, PA). *Surg. Gynecol. Obstet.* 141(5):724-726; 1975.

The hypothesis that the hypocalcemia occurring in acute pancreatitis is caused by thyrocalcitonin release, which is mediated by glucagon secreted from the inflamed pancreas, was tested in thyroidectomized and nonoperated pigs with chemically-induced pancreatitis. Pancreatitis was induced using 20 ml of 7% sodium taurocholate solution containing 20,000 U of trypsin. No significant difference was seen in the average fall in serum calcium concentration between five thyroidectomized pigs (1.56 ± 0.25 mg%) and thyroid-intact pigs (1.49 ± 0.19 mg%) at 24 hr after the induction of pancreatitis. Between 24 and 48 hr, the serum calcium levels of the thyroidectomized pigs gradually returned toward the baseline, while those in the thyroid-intact pigs continued to drop. By 48 hr, the serum calcium level in the thyroidectomized pigs was 0.90 ± 0.57 mg%, compared with 1.83 ± 0.38 mg% in the thyroid-intact pigs ($p<0.01$). Serum thyroxine levels averaged 1.9 mg% prior to thyroidectomy and at the time of induction of pancreatitis. The differences observed in the degree of hypocalcemia between the two groups 24-48 hr after the induction of pancreatitis may be significant, but could be explained by dilutional differences alone. Thyrocalcitonin apparently has little, if any, role in the hypocalcemia observed during the course of acute pancreatitis.

5841 BEHAVIOR OF URINARY KALLIKREIN DURING ACUTE PANCREATITIS. (Ita.) Butti, A.; Ronzoni, G.; Porcelli, G.; Pigliucci, G. M.; Maria, G. (Istituto di Clinica Chirurgica Generale e Terapia Chirurgica, Univ. Cattolica del Sacro Cuore, Rome, Italy). *Chir. Patol. Sper.* 22(5):302-307; 1974.

Urinary kallikrein was measured spectrophotometrically by its esterase activity in 12 patients (7 women and 5 men, aged 22-56) with acute pancreatitis. Results were comparable to those in 24 normal individuals used as controls. Even though plasma kallikrein activity increases in acute pancreatitis, it is apparently blocked at the level of the kidney. Since kallikrein has a molecular weight of about 37,000-40,000, it may be that the kallikrein molecule cannot filter through the kidney. The data confirm that the renal secretion of kallikrein is completely independent of plasma kallikrein levels.

5842 THE ROLE OF BILIARY MICROLITHIASIS IN ACUTE PANCREATITIS. A STUDY OF A SERIES OF 31 CASES. (Fre.) Mouiel, J.; Chauvin, P.; Borelli, J.-P.; Bus, J.-J.; Giaume, F.; Bourgeon,

R. (Hopital Saint Roch, 06000 Nice, France). *Chirurgie* 101(4):258-265; 1975.

Biliary microlithiasis has been found to be a factor in the development of 80% of acute pancreatitis (31/38 patients) observed over the past 3 yr. Three case histories are reported. Systematic peroperative exploration should be undertaken by opening the gallbladder and the common bile duct even in the absence of radiological symptoms, as was the case in nine patients. Treatment should immediately relieve canalicular hyperpressure; cholecystectomy and drainage choledocotomy are systematic. Prognosis was determined by the presence of pancreatic necrosis, which was not uncommon, and explained the high mortality rate (9/31). Acute pancreatitis may be of retrograde origin, as a result of lithiasis of the main bile duct or of lesions of the bile duct, which are indicative of lithiasic migration and evidence of biliary reflux into the Wirsung canal (2/3 cases).

5843 SPECIFIC LYMPHOCYTE SENSITIZATION IN CHRONIC PANCREATITIS. (Eng.) Schutt, C.; Friemel, H.; Schulze, H. A.; Zubaidi, G. (Inst. Biochemistry, Univ. Rostock, Leninallee 70, DDR-25, Rostock, E. Germany). *Digestion* 13(5):308-311; 1975.

An *in vitro* test for the detection of specific lymphocyte sensitization in chronic pancreatitis was carried out in the lymphocytes of normal persons, patients with chronic pancreatitis, acute exacerbations of chronic pancreatitis, and acute pancreatitis, and in the lymphocytes of patients with other diseases. Peripheral blood lymphocytes from the heparinized blood of 47 subjects were cultured and stimulated with specific human pancreas antigens. Sixty-eight tests were performed. If the lymphocytes are sensitized *in vivo* during pancreatic destruction, they are transformed to blast cells during this test. The degree of blast transformation is measured by the DNA synthesis rate. Significant positive results were found only in cases of chronic pancreatitis. The results obtained to date suggest that the lymphocyte transformation test is helpful in correctly diagnosing chronic pancreatitis. No further preparation of the organ-specific proteins appears necessary for this diagnostic procedure. It may be possible to distinguish chronic pancreatitis from pancreatic carcinoma by an extension of this immunological study.

5844 LYMPHOCYTE SENSITIZATION IN HUMAN CHRONIC PANCREATITIS. (Ita.) Gulla, P.; Marocco, A. (Istituto di Clinica Chirurgica e Terapia Chirurgica dell'Univ. di Perugia, Perugia, Italy). *Acta. Chir. Ital.* 31(1):57-62; 1975.

To determine if the pathogenesis of chronic human pancreatitis has an autoimmune basis, lymphoblast transformation was studied in 10 patients with the disease and in 10 normal controls; the Coulson and Chalmers procedure was followed. In cultures containing lymphocytes only, blast transformation was either minimal or nonexistent. In cultures with lymphocytes and phytohemagglutinin, blast transformation was about 60%. In lymphocyte and antigen cultures, the percentage was 15% in patients in both chronic and acute stages. Cultures from the controls had a blast transformation of about 2%. The results demonstrate a moderate immune response in chronic pancreatitis whose function may be the maintenance of a chronic inflammatory process of the pancreas previously damaged in the initial clinically apparent phase.

5869 THE ABNORMAL HEPATIC SCAN OF CHRONIC LIVER DISEASE: ITS RELATIONSHIP TO HEPATIC HEMODYNAMICS AND COLLOID EXTRACTION. (Eng.) Horisawa, M.; Goldstein, G.; Waxman, A.; Reynolds, T. (Nagoya Univ. Sch. Medicine, Nagoya, Japan). *Gastroenterology* 71(2):210-213; 1976.

To elucidate the characteristic hepatic scan pattern of chronic liver disease, the degree of scan abnormality (scan score, SS) after the administration of technetium-99m sulfur colloid (Tc) was compared with data obtained at hepatic vein catheterization in 28 patients. Although SS showed a correlation with wedged hepatic vein pressure (r=+0.491), the scan abnormality was not directly due to portal hypertension, because it remained unchanged when the latter was relieved by portacaval shunt. Since SS showed a poor positive correlation with hepatic blood flow (r=0.262), the scan abnormality was unrelated to a low hepatic blood flow. Scan abnormality was not attributable primarily to hyperactivity of the reticuloendothelial (RE) cells of the spleen and bone marrow, since fractional clearance (K) of Tc from the blood was decreased (K ranged between 0.007 and 0.220) rather than increased in patients with abnormal scans. SS was inversely correlated with K of Tc (r=-0.575) and with hepatic extraction efficiency for Tc (r=-0.673), showing that the basic abnormality was poor extraction of the colloid by the RE cells of the liver, with a resultant increase in the amount available for extrahepatic localization. Indirect evidence suggests that this poor extraction of colloid is due to intrahepatic shunts bypassing hepatic RE cells.

5870 CONTROLLED CLINICAL EXPERIMENTATION WITH 2-MERCAPTO-PROPIONYLGLYCINE (THIOLA) IN CHRONIC LIVER DISEASE. (Ita.) Dioguardi, N.; Ideo, G.; Roda, E.; Ronchi, G.; Labo, G.; Barbara, L.; Gasbarrini, G.; Roda, E.; Miglio, F.; Ventura, E.; Agnolucci, M. T.; Zeneroli, M. L.; Albano, O.; Leo, M.; Muiesan, G.; Corea, L.; Agabati-Rosei, E.; Sala, G.; Mandelli, M.; Curzio, M.; Avogaro, P.; Pasquino, M. (Istituto Clinica Medica III, Via Pace 15, Milan, Italy). *Minerva Med.* 67(11):676-681; 1976.

To test the effects of 2-mercapto-propionyl-glycine (2-MPG) in chronic liver disease, a group of patients with persistent chronic liver disease (group I) and a group with aggressive chronic hepatitis and compensated hepatic cirrhosis (group II) received 2.5 g of 2-MPG, i.v., or placebo/day, and vitamin B_{12}. In patients treated with 2-MPG, transaminase serum levels fell significantly by the end of treatment. BSP retention was improved by 2-MPG, especially in group II. Bilirubinemia was reduced, especially in group II, by 2-MPG or placebo, suggesting that bed rest was probably the causal factor. Other biochemical parameters, such as cholesterolemia, prothrombinic activity, and total proteinemia were not significantly modified. The inhibitory action of 2-MPG is probably related to its antioxidant action; the significant reduction of transaminases suggests that its main pharmacological effect is the protection of the hepatocytic membrane. Improved BSP clearance is either due to 2-MPG protection of the hepatocytic membrane or to competition with reduced glutathione as a donor of hydrogen ions.

5871 BARBITURATES: LIVER AND BILE SECRETION. (Fre.) Plomteux, G.; Crismer, R. (Laboratoire de Chimie medicale, 1, rue des Bonnes Villes, B 4000 Liege, Belgium). *Ann. Gastroenterol. Hepatol.* 12(2):81-89; 1976.

The action of barbiturates on the liver enzymes and the physiologic and pharmacologic consequences are reviewed. Biochemical and pharmacological data show that barbiturates stimulate glucuronyltransferase activity in hepatocytes. Thus, they can significantly reduce hyperbilirubinemia in jaundice with free bilirubin, essentially Gilbert's and Dubin-Johnson's syndromes, and Crigler-Najjar neonatal jaundice. Since barbiturates also act as inductors of the microsomal enzymes, which detoxify certain drugs, such as alcohol, bishydroxycoumarin, diphenylhydantoin, and steroids, drug combination therapy with barbiturates may be ineffective. They possess a choleretic effect, which may be of use in the treatment of hepatic cholestases.

5872 EXAGGERATED PANCREATIC RESPONSE TO SECRETIN. (Fre.) Wettendorff, P.; van der Hoeden, R.; Delcourt, A. (Institut medico-chirurgical Ixelles, rue Jean Paquot 63, B-1050 Bruxelles, Belgium). *Acta Gastroenterol. Belg.* 37(12):520-528; 1974.

The pancreas of 250 patients was successively stimulated with Boots and GIH secretin (1 U/kg, i.v.). Bicarbonate parameters measured in the duodenal fluid were bicarbonate flow rate and maximum bicarbonate concentration. Eleven patients had an excessive reaction to the hormone with an increase in bicarbonate concentration. In seven of these patients (1 with Zeive's syndrome, 1 with pancreatitis with hepatic steatosis, and 5 with alcoholic cirrhosis), the maximum concentration was under or near the lower limit of the norm; the reaction was of biliary origin. In the remaining patients (4 with pancreatitis with first signs of recurrence), the reaction was of pancreatic origin, and the maximum bicarbonate concentration was normal. The reaction may be due either to a decrease in the capacity of the liver to inactivate the hormone, to a hypersensitivity of the receptor cells, or to an increase in the number of cells.

5873 A COMPARATIVE CLINICAL STUDY OF ALKALINE PHOSPHATASE ISOENZYMES AND SERUM 5'-NUCLEOTIDASE IN HEPATOBILIARY DISEASE: 544 COMBINED DETERMINATIONS. (Fre.) Metman, E. H. (C.H.U., Tours, France). *Rev. Fr. Gastroenterol.* (107):7-10, 13-16, 19-22; 1975.

Serum of 424 patients with various hepatic and biliary pathologies was examined to compare alkaline phosphatase and 5'nucleotidase enzymes. Automatic spectrophotometric determination was used for the former, and a method using differential inhibition with nickel for the latter. Controls numbered 60. Results show for alkaline phosphatase and 5'nucleotidase, resp., percentages of 100% and 90% in extrahepatic retentional jaundice, 100% and 100% in cancer of the bone and liver, 100% and 100% in intrahepatic cholestasis, 83% and 60% in cytolytic viral hepatitis, 82% and 73% in primary or secondary cancer of the liver, 80% and 80% in nonalcoholic cirrhosis, 85% and 20% in bone pathologies, 15% and 27% in alcoholic subjects, 62% and 50% in cirrhosis, 71% and 45% in cirrhosis with jaundice, 32% and 37% in diabetes, 48% and 44% in other pathologies, and 51% and 45% in other cancers. These results support the parallel rise of both enzymes in hepatic and biliary pathologies and the absence of a rise in 5'nucleotidase in bone pathologies. In extrahepatic obstructions, 10% of cases had normal 5'nucleotidase but an elevated alkaline phosphatase. A good correlation was found between the latter enzyme and jaundice in cirrhosis. On the other hand, 5'nucleotidase was more accurate an indicator in chronic alcoholism. In diagnosis, the enzymes must complement each other as the hepatic selectiveness and greater sensitivity of 5'nucleotidase is accompanied by less cholestatic specificity.

5874 ALPHA FETOPROTEIN IN LIVER DISEASE IN PAPUA NEW GUINEA. (Eng.) Woodfield, D. G.; Endo, Y.; Clarke, C. (Red Cross Blood Transfusion Service, P.O. Box 1174, Boroko, Papua, New Guinea). *Aust. N.Z. J. Med.* 6(2):117-120; 1976.

The sera of 112 patients with proven liver disease, 84 normal blood donors, 69 healthy village subjects, and 30 patients without liver diease were analyzed for alpha fetoprotein (AFP) by radioimmunoassay. All of the 84 blood donors had AFP values within the normal range; in the remaining 99 subjects without liver disease, 9% had elevated AFP levels, but in only one case did the level exceed 400 ng/ml. Of 23 patients with viral hepatitis, the AFP level exceeded 20 ng/ml in 25%, and in 3 patients, the level exceeded 400 ng/ml. None of these patients had a positive immunodiffusion test for AFP. Of 18 patients with cirrhosis, 72.2% had elevated AFP values; one-third of the 18 patients had values above 400 ng/ml. One cirrhotic patient had a positive immunodiffusion test. In 31 patients with primary liver cell carcinoma, the AFP levels were raised in 96.8%. Twenty-six of the 31 patients also gave positive results by immunodiffusion testing. The AFP level was raised in 20% of 20 patients with liver disease and with normal liver histology. In 5 of 20 patients with nonspecific liver changes, the level was raised. The results indicate that elevated AFP levels are found in various liver diseases, but particularly in primary liver cell carcinoma.

5875 SIGNIFICANCE OF ALPHA-FETOPROTEIN DETERMINATIONS IN PATIENTS WITH LIVER DISEASES. (Ger.) Lamerz, R.; Schmalhorst, U.; Grunst, J.; Fateh-Moghadam, A.; Eisenburg, J. (I. Med. Univ.-Klinik, Ziemssenstrasse 1, Munich, W. Germany). *Fortschr. Med.* 94(12):702-710; 1976.

An alpha-fetoprotein (AFP) radioimmunoassay technique of improved sensitivity was developed and employed in the examination of patients with various liver diseases. Immunologically pure AFP was administered to rabbits to produce high-titer monospecific anti-AFP sera. The purified AFP and the corresponding antibody were employed in a competitive radioimmunoassay, according to the double antibody method. Serum AFP levels were below 5 ng/ml in 121 of 140 normal sera, and between 5 and 14 ng/ml in the other 19. Of 18 patients with primary hepatocellular carcinoma, 7 had serum AFP levels above 10,000 ng/ml (i.e., in the Ochterlony-positive range), 7 had levels between 1,000 and 7,000 ng/ml, 3 showed moderate elevations at 21-120 ng/ml, and a normal serum AFP level was seen in 1 patient 2 yr after tumor resection. Other clinical-chemical parameters were not correlated with AFP levels nor were the size or extent of the tumor in the six cases in which autopsies were performed. Normal serum AFP levels were determined in 9 of 15 patients with liver metastases, and moderately elevated levels of up to 111 ng/ml were seen in the other 6 patients. Serum AFP levels below 20 ng/ml were found in 90 of 102 liver cirrhosis patients, and elevated levels (up to 134 ng/ml) were seen in 12 cases. Early hepatoma was suspected in three cirrhosis patients with AFP levels above 1,000 ng/ml, and was later confirmed. Transient AFP increases of 20-238 ng/ml were seen in 32% of the cases in the early stage of acute hepatitis, while 65% of the patients displayed values within this range at some time during follow-up (performed in 31 cases). Similar results were seen in three of seven cases of chronic hepatitis. Maximum AFP levels were developed 5-18 days after the maximum transaminase activities and coincided with a decrease in cholinesterase levels. Radioimmunologic AFP determinations in liver cirrhosis may permit early recognition of developing primary liver carcinoma.

5876 VALUE OF DETERMINATION OF THE GAMMA-GLUTAMYLTRANSPEPTIDASE (G.G.T.) ACTIVITY IN HEPATOBILIARY PATHOLOGY. REPORT OF OVER 5,000 DETERMINATIONS. (Fre.) Lafargue, P.; Couture, J.-C.; Ponsot, P. (Hopital Percy, 101 avenue H. Barbusse, F 92141 Clamart Cedex, France). *Nouv. Presse Med.* 5(27):1697-1698; 1976.

The determination of the serum activity of gamma-glutamyltranspeptidase (GGT) is of diagnostic use in cholestatic syndromes. However, only values greater than 90 mIU/ml are significant. Variations in GGT activity are as sensitive and more specific than those of alkaline phosphatase, more sensitive and as specific as those of leucine aminopeptidase, and as sensitive, specific, and early as those of 5'-nucleotidase. Abnormally high or rising GGT values may indicate primary or metastatic hepatic cancer justifying the repetition of hepatic scintigraphies. GGT activity can reveal alcohol as a cause of liver intoxication, especially at precirrhotic stages.

5877 THE BIOCHEMICAL PATHOLOGY OF LIVER CELL NECROSIS. (Eng.) Farber, J. L.; El-Mofty, S. K. (Temple Univ. Health Sciences Center, 3400 North Broad St., Phila., PA 19140). *Am. J. Pathol.* 81(1):237-250; 1975.

The biochemical pathology of liver cell death is reviewed, and a hypothesis based on a galactosamine-induced liver cell necrosis is presented. Many forms of severe liver cell damage are unaccompanied by necrosis, such as ethionine poisoning or low doses of galactosamine. Studies with puromycin, cycloheximide, and tenuazonic acid indicate that inhibition of protein and RNA synthesis is not associated with cell death, and that liver cells can tolerate low ATP levels, accumulation of fat, and disturbances in ion transport for many hours. Mitochondria and lysosomes have been ruled out as primary targets for the molecular mechanisms of cell death by studies of the time course of damage to these organelles after cell poisoning. Evidence indicates that one of the earliest events of cell death by carbon tetrachloride is a destructive attack on the cell membranes, followed by an increase in the calcium content. Membranes from hepatocytes are abnormal 3 hr after administration of dimethylnitrosamine. These and other studies have shown that the plasma membrane and its presumed role in maintaining a proper Ca^{++} balance is the primary site of irreversible hepatocyte damage. Galactosamine damage was used as a model to study hepatocyte death in rats. Membranes from rats given a low dose of galactosamine (200 mg/kg) were normal, but those from rats given a high dose (400 mg/kg) showed a 40% reduction in specific activity of 5'-nucleotidase and a twofold increase in the maximum negative ellipticity, determined by circular dichroism, as early as 2 hr after administration. Galactosamine membrane damage fulfilled criteria for a causal relationship to cell death, in that it was dose-dependent and reversible by uridine, in parallel with uridine's ability to prevent cell death. Loss of responsiveness to uridine coincident with loss of reversibility distinguished membrane changes from other biochemical disturbances and suggested that the plasma membrane may be the primary target. Changes in the calcium concentration were dose-dependent, rising between the second and third hours after administration in rats given the high dose, and falling in those given the low dose. Calcium increase was prevented by uridine until 2.5 hr after administration of galactosamine. It is proposed that galactosamine produces a deficiency of uridine nucleotides, uridine diphosphate-hexoses, and increased uridine diphosphate-hexosamines, which lead to injury of the plasma membrane and increases in Ca^{++} concentration. At 2.5 hr after administration, the injury becomes irreversible and leads to cell death.

5878 DISSEMINATED INTRAVASCULAR COAGULATION AND HEPATIC NECROSIS: COMPLICATIONS OF INFECTIOUS MONONUCLEOSIS. (Eng.) Pelletier, L. L., Jr.; Borel, D. M.; Romig, D. A.; Liu, C. (Univ. Kansas Sch. Medicine, Kansas City, KS 66103). *JAMA* 235(11): 1144-1146; 1976.

The case of a 48-yr-old man, who died from disseminated intravascular coagulation (DIC) and hepatic necrosis complicating infectious mononucleosis, is reported. The patient presented with fever, malaise, dyspnea, anasarca, and orthopnea, for which he was treated with ampicillin, and later with dexamethasone sodium phosphate. The symptoms recurred after this therapy was discontinued; progressive jaundice, somnolence, and petechiae developed. A necrotic white membrane in the pharynx, hepatosplenomegaly, and generalized lymphadenopathy were also present. During the 4 hospital days before his death, therapy consisted of a continuous i.v. infusion of heparin sodium (750 or 375 U/hr); methylprednisolone (125 mg/8 hr); plasma, platelet, and RBC transfusions; gentamicin sulfate; and clindamycin hydrochloride hydrate. Autopsy revealed extensive cutaneous and serosal petechiae, intra-alveolar hemorrhage into the left upper lobe of the lung, recent bleeding into the soft tissues of the pelvis, and blood within the gastrointestinal tract. A diffuse vasculitis involved the veins and venules of the uvula, tonsils, testes, lymph nodes, and spleen. Large numbers of arteriolar and capillary fibrin thrombi occurred in the liver, lymph nodes, heart, renal glomeruli, and spleen. The liver was enlarged, and intravascular fibrin thrombi were present within nearly every hepatic portal space and periportal sinusoid. There was extensive confluent periportal coagulative necrosis and degeneration, with necrosis of interlobular bile ducts and cholangioles, associated with moderate infiltration of the periportal areas of atypical lymphocytes. The relative lack of cellular infiltration of the liver and the generalized lymphoid atrophy may reflect the lympholytic effect of the administration of high doses of adrenal corticosteroids. The presence of DIC and the remarkable extent of intravascular fibrin deposition in the liver suggest that liver necrosis may have resulted from hepatic infarction produced by the intravascular thrombi formed in response to a generalized vasculitis.

5879 THE LIVER AND DEFICIENCY IN ALPHA-1-ANTITRYPSIN. (Fre.) Traissac, F.-J.; Paccalin, J.; Terme, R. (No affiliation given). *Bordeaux Med.* 8(10):1191-1198; 1975.

The association between a genetic deficit in serum α_1-antitrypsin (AAT), which is expressed in the phenotype protease inhibitor zero (PIZZ), and either pulmonary diseases (panlobular emphysema), hepatic diseases (infantile cirrhosis, neonatal hepatitis, cirrhosis and hepatic fibrosis, primary liver cancer), or both was examined, and its specific anatomopathologic signs reviewed. Conventional microscopy shows a reduced number of ribosomes on the endoplasmic reticulum in the hepatocyte. The endoplasmic reticulum is dilated due to the accumulation of globules, which are secreted by the ribosomes and which are antigenically like AAT. The endoplasmic reticulum appears normal in the absence of these agglomerates. The accumulation of such globules is not pathogenic in itself, as it sometimes occurs in normal cells, but here the globules are not excreted normally from the hepatocyte. The anomaly probably lies in the hydrocarbon portion of the molecule, which is crucial in transport mechanisms. Sialic acid may not bind normally either, because of the malformation of a protein chain or because of the dysfunction of a glycosyltransferase.

5880 ALPHA 1 ANTITRYPSIN DEFICIENCY IN CHILDREN: ULTRASTRUCTURE OF THE LIVER AND SPECULATIONS. (Fre.) Scotto, J. M.; Stralin, H. G.; Alagille D. (U-56 INSERM, Hopital de Bicetre, F-94270 Le Kremlin Bicetre, France). *Virchows Arch. [Pathol. Anat.]* 369(1):19-27; 1975.

Twelve children with liver diseases associated with a PiZZ phenotype alpha 1 antitrypsin serum deficiency underwent hepatic biopsies. Samples were studied by electron microscopy. A homogeneous material was found in some hepatocytes of all samples. Deposits of this material in the perinuclear spaces of the hepatocytes caused intranuclear invaginations, but more was observed in the lumens of the endoplasmic reticulum. There were occasional groups of ribosomes attached to the smooth and rough reticular membranes surrounding other sites of deposit, however, the smooth endoplasmic reticulum appears directly implicated in the depositing process. With regard to the PiZZ phenotype, the abnormal substance seems to be a form of normal alpha 1 antitrypsin, deprived of sialic acid, and the disorder may result from imperfect synthesis of a glycoprotein. The ultrastructural data observed does not corroborate biochemical studies, which situate the first binding steps of the monosaccharide residues at the level of the rough endoplasmic reticulum.

5881 BONE METASTASES REVEALING HEPATOMA. REPORT OF SIX CASES. (Fre.) Joubaud, F.; Ben Bouali, A.; Cheguillaume, J.; Minier, J.-F.; Lavenet, C. (No affiliation given). *Ouest Med.* 28(16):1139-1142; 1975.

A study is presented of six patients (5 men and 1 woman, median age 59 yr) with bone metastases revealing primary hepatomas. While three patients had liver function evidence of cirrhosis, there was no clinical data to help determine the etiology of the metastases in the other three. Initial clinical symptomatology was marked by bone fractures in two patients, and by pains in the vertebral column in four. Biological examinations were basically normal and functional hepatic exploration uninformative. However, radiology was useful in confirming the metastases and defining their location. Scintigraphic exploration of the liver with double markers (^{99m}Tc and ^{75}Se) diagnosed the primary hepatoma.

5882 MINIMAL DEVIATION HEPATOMA: A NEW ENTITY. (Eng.) Galloway, S. J.; Casarella, W. J.; Lattes, R.; Seaman, W. B. (Hosp. St. Raphael, 1450 Chapel St., New Haven, CT 06511). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 125(1): 184-192; 1975.

The cases of four women (aged 30-67 yr) with liver tumors, only one of whom had a history of oral contraceptives, are presented. The authors suggest the term minimal deviation hepatoma (MDH) to describe these tumors, which have been previously call hemartoma, adenoma, and benign hepatoma. None of the women had a history of liver disease. Angiographically, lesions which were hypervascular had large feeding arteries, which began peripherally in the mass and coursed centripetally toward the center. Permeating neovascularity, which is seen in malignant hepatomas, was not observed. The lack of venous laking, arteriovenous shunting, and portal vein invasion distinguished these lesions from malignant ones. Other masses were principally avascular. Single and multiple nodules were seen. Each mass was well demarcated from adjacent normal tissue in the capillary phase of the angiogram. Some lesions were located deep in the liver substance, while others were subcapsular or pedunculated and were associated with subcapsular hematomas. The four cases presented here, and 19 previously reported cases, represent a distinct clinical and pathological entity. Clinically, the patients are usually female, young, with no known preexisting liver disease. Liver function studies are normal or minimally deranged. Fever indicates an underlying necrosis, and anemia may reflect blood loss. Hemorrhage and shock may occur with the rupture of a superficial mass. Usually, the presenting complaint is a falling hematocrit or an enlarging mass. Although hormonal influence has been implicated in these tumors, no causal relationship has been firmly established. Three of these cases represent the first report of MDH in women not taking oral contraceptives. Therapy should be directed toward limited resection of accessible lesions, as radical resection may carry a greater morbidity than may the lesion itself. Nonrestricted masses with cellular atypia may be given a trial of chemotherapy, with hope of regression and cure. Untreated lesions may rupture. When a previously healthy woman presents with a right upper quadrant mass, epigastric pain, a defect in the liver scan, or a hemoperitoneum, the diagnosis of MDH should be considered and verified by angiography.

5883 HEPATIC ARTERY LIGATION AND PROLONGED CYTOTOXIC THERAPY IN ADVANCED PRIMARY AND SECONDARY LIVER TUMOURS. (Eng.) Cuschieri, A.; Swain, C.; Crosbie, R. B. (Dept. Surgery, Univ. Liverpool, PO Box 147, Liverpool, L69 3BX, England). *Proc. R. Soc. Med.* 68(11):678-680; 1975.

Experience with hepatic artery ligation and infusion chemotherapy in the treatment of 17 patients with advanced hepatic malignancies is presented. The series included five patients with inoperable primary liver tumors (3 with hepatocellular carcinoma, 2 with cholangiocarcinoma) and 12 with massive secondary hepatic involvement (colorectal, 8; gastric, 1; adrenal, 1; unknown, 2). The output volume of the chemofusor used in the administration of 5-fluorouracil was 5.0 ml/24 hr, equivalent to a maximum daily dose of 250 mg. Infusion therapy was continued for 6 weeks. Four patients received a shorter course of treatment due to dislodgement of the catheter from the hepatic artery, while six patients received an additional course of methotrexate (500 mg over 10 days) at the end of the 6 weeks. There was only one postoperative death. Transient derangement of liver function, accompanied by fever and leukocytosis, was common in patients with metastatic disease. The preoperative serum bilirubin and alanine aminotransferase levels rose from 2.4 mg/100 ml and 122.0 IU/100 ml, resp., to 3.8 mg/100 ml and 1,070.6 IU/100 ml, resp., postoperatively, and the average WBC count rose from 7,800/mm^3 before surgery to 16,700/mm^3 after surgery. These changes largely subsided within 14 days of surgery. Six patients with metastatic disease showed an objective response to treatment and experienced relief of pain. The mean survival was 9.0 months for these patients and 2.2 months for the other patients with metastatic disease. Survival ranged between 4 weeks and 18 months in the patients with primary hepatoma. Two patients died from massive tumor pulmonary emboli within the first 5 weeks after surgery. The results suggest that hepatic artery ligation and prolonged infusion chemotherapy may provide worthwhile palliation to patients with advanced hepatic malignancy.

5884 EVALUATION OF SCLEROSING CHOLANGITIS BY ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY.

(Eng.) Ruskin, R. B.; Katon, R. M.; Bilbao, M. K.; Smith, F. (Hayward California Permanente Medical Group, Hayward, CA). *Arch. Intern. Med.* 136(2):232-235; 1976.

Two cases of sclerosing cholangitis, with a biliary tree well visualized by endoscopic retrograde cholangiopancreatography (ERCP), are described. In the first patient, a 43-yr-old man with long-standing biliary tract disease, sclerosing cholangitis was diagnosed after T-tube cholangiography and histologic examination of a liver biopsy specimen. Because of a rising serum alkaline phosphatase value and pruritus, the progress of the disease was assessed by ERCP 2 yr after the initial diagnosis. The retroduodenal portion of the common bile duct was substantially narrowed and beaded. Above the duodenum, the major ducts were dilated. The intrahepatic branches were narrow and irregular. These abnormalities were slightly more severe than those observed 2 yr previously, but were considered indistinguishable from differences that were caused by the degree of distention. In the absence of clinical, histologic, or definite cholangiographic progression during the previous 2 yr, surgical intervention was not indicated. One year later, the patient was again evaluated by ERCP because of increasing fatigue, pruritus, and conjugated hyperbilirubinemia. An unmistakable progression of both the narrowing of the retroduodenal bile duct and the dilatation above was demonstrated; a choledochojejunal shunt was successfully performed. In the second patient, a 46-yr-old man, ERCP showed a striking, irregular narrowing of the common bile duct that emptied into a deformed duodenal diverticulum. There were multiple irregular stenoses and saccular dilatations of the major hepatic ducts; the intrahepatic ducts were diffusely narrowed and irregular. The gallbladder appeared normal. These findings were consistent with sclerosing cholangitis or bile duct carcinoma, and exploratory laparotomy was performed. Cholecystoduodenostomy was done, and histologic examination confirmed the diagnosis of sclerosing cholangitis. When intrahepatic involvement is present, ERCP may provide the only means for following the course of this disease short of laparotomy.

5885 BENIGN POSTOPERATIVE INTRAHEPATIC CHOLESTASIS

(Fre.) Najman, A. (Hopital Saint-Antoine, 184, rue du Faubourg-Saint-Antoine, F 75571 Paris Cedex 12, France). *Nouv. Presse Med.* 4(43):3073-3074; 1975.

A hemophiliac, who had suffered a fall, developed a large hematoma on his right side and right lumbar region. When the liver receives a massive and sudden dose of bilirubin, as can be caused by a massive hematoma, clinical symptoms can be identical to those of a benign postoperative intrahepatic cholestasis. The patient also developed jaundice, caused by a massive overload of bilirubin in the liver (600 mg/l total bilirubin in the blood, 60 mg/l free bilirubin). Conjugation continued normally; there were no mechanical obstacles in the bile ducts. There was a temporary hepatic functional disability (transitory prothrombin deficiency). Within a month, the patient recovered with repeated blood transfusions.

5886 CHRONIC PRIMARY INTRAHEPATIC CHOLESTASIS: PATHOLOGY STUDY OF 11 PATIENTS.

(Fre.) Baglin, A. C.; Lemaigre, G.; Abelanet, R.; Galian, P. (C.H.U. Cochin, Port-Royal, Paris). *Ann. Anat. Pathol. (Paris)* 20(1):57-73; 1975.

Eleven women (average age, 44.5 yr) with apparent primary chronic intrahepatic cholestasis underwent surgical biopsy. Results showed two distinct histological groups. In the first group (3 patients), lesions were disparate, aspecific, and difficult to define. In the second (8 patients), the lesions were stereotyped. They were epithelial and segmentary lesions of the biliary canals, accompanied by characteristic but variable cell infiltrates. These lesions evolved into mutilating sclerosis with progressive loss of inflammatory lesions. Antimitochondrial antibodies were frequently associated with the histology observed in the second group. Clinical symptoms were also similar in the second group of patients and included severe pruritus, followed by early or late icterus, asthenia, and hepatomegaly. Death ensued 5-7 yr after onset of disease despite corticoid and chloraminophen therapy.

5887 EFFECT OF DIALYSIS OF MEDIUM-SIZED MOLECULES ON ENCEPHALOPATHY IN THE COURSE OF COMA DUE TO ACUTE HEPATIC ATROPHY: PRELIMINARY RESULTS.

(Fre.) Opolon, P.; Lavallard, M. C.; Crubille, C.; Gateau, Ph.; Nusinovici, V.; Granger, A.; Darnis, F.; Caroli, J. (Service d'exploration neurophysiologique, C.H.U. St-Antoine, France). *Med. Chir. Dig.* (Suppl. 2):37-41; 1975.

Cerebral function was studied in 11 patients with acute hepatitis in a state III (1) or IV (10) coma treated by hemodialysis with a polyacrylonitrile membrane to remove medium size molecules. Sessions were daily or every 2-3 days over a period of 30 days, and they usually were initiated 2-48 hr after onset of coma. Supportive treatment consisted of glucose antacids, lactulose, and blood transfusions. Furosemide, 20-40 mg, i.v., was administered as required to maintain adequate diuresis. Brain death occurred in four patients before the end of the series of dialysis treatments. Of the remaining seven patients, five completely regained consciousness and two partially regained consciousness for a period of 24 hr to recovery. Death as a result of massive hepatic destruction occurred in five of seven patients who benefited from hemodialysis; two survived more than 40 days after onset of illness (1 survived with a persistent hepatitis for 8 months). Hemodialysis was sometimes beneficial in the cases of massive hepatic destruction and in aged patients. Plasma concentrations of amino acids before and after dialysis as well as dialysate concentrations are tabulated.

5888 ASPECTS OF BILE ACID METABOLISM IN CYSTIC FIBROSIS.

(Eng.) Goodchild, M. C.; Murphy, G. M.; Howell, A. M.; Nutter, S. A.; Anderson, C. M. (Inst. Child Health, Univ. Birmingham, Francis Road, Birmingham B16 8ET, England). *Arch. Dis. Child.* 50(10):769-778; 1975.

Bile acid metabolism was investigated in 29 cystic fibrosis (CF) patients and 4 non-CF patients with pancreatic enzyme insufficiency to relate bile acid findings in feces, duodenal fluid, and serum to the liver disease and steatorrhea of CF. Three-day-old fecal collections from all patients were analyzed for fat and total bile acid content. Serological liver function tests were performed on all patients, and duodenal and serum bile acid studies were made by intubation at the time of investigation of pancreatic function. There was a significant increase in CF 3-alpha-hydroxy fecal bile acid values (47.6 ± 37 μmol/kg/24 hr) compared with controls (18.0 ± 2.8 μmol/kg/24 hr, $p<0.001$). Eighteen of the 29 CF patients had fecal bile acid values greater than the mean for the control group. Two of the four non-CF patients with pancreatic enzyme insufficiency also had raised fecal bile acid excretions. Fecal fat excretions were 20.3 ± 11.3 g/24 hr for the CF patients, 3.0 ± 1.0 for the control subjects ($p=0.001$), and 11.3 g/24 hr for the four non-CF patients. No correlation was found between fecal bile acid and fecal fat excretion for either of the two patient groups or for the controls. Fecal bile acid excretion showed an inverse relation with age in the CF patients, but not in the control subjects. The CF patients with overt liver disease tended to have the lowest fecal bile acid values. Duodenal aspiration in five CF patients and in one non-CF patient with pancreatic enzyme insufficiency (Shwachman-Diamond syndrome) produced very small fluid volumes. Duodenal fluid mean total bile acid concentrations were within normal limits. Estimation of serum bile acids in these six patients showed that three had raised bile acid values. Fecal analysis confirms previous findings of increased fecal bile acid loss in CF.

5889 EFFECTS OF KETO ANALOGUES OF ESSENTIAL AMINO ACIDS IN PORTAL-SYSTEMIC ENCEPHALOPATHY.

(Eng.) Maddrey, W. C.; Weber, F. L., Jr.; Coulter, A. W.; Chura, C. M.; Chapanis, N. P.; Walser, M. (Johns Hopkins Hosp., 601 N. Broadway, Baltimore, MD 21205). *Gastroenterology* 71(2):190-195; 1976.

The efficacy of using α-keto analogues of amino acids in the management of patients with portal-systemic encephalopathy was evaluated. Keto analogues of five essential amino acids (valine, leucine, isoleucine, methionine, and phenylalanine) were given either i.v. or p.o. in varying proportions to 11 patients with portal-systemic encephalopathy and hyperammonemia. When the sodium salts of these acids, plus L-histidine, L-threonine, L-tryptophan, L-lysine monohydrochloride, and L-arginine, were administered i.v., the doses were: 0.97, 1.29, 0.88, 1.27, 1.25, 0.50, 0.25, 0.54, 0.80, and 0.00 for sodium α-keto-isovalerate, sodium α-ketoisocaproate, sodium α-keto-β-methylvalerate, sodium α-keto-β-methylthiobutyrate, sodium phenylpyruvate, L-threonine, L-tryptophan, L-histidine, L-lysine, and L-arginine, resp. For p.o. administration, the branched chain keto analogues were given in 3-4 times greater quantities; the other analogues were given in 1.5 times the amounts in the i.v. solution. Plasma concentrations of amino acids corresponding to the infused analogues, including alloisoleucine, increased significantly after infusions. Plasma tyrosine and glycine, which were abnormally elevated in control samples, fell after the infusions. After one to five daily infusions, the ratio of essential to nonessential amino acids in fasting plasma was increased toward normal, suggesting improved protein nutrition. Arterial blood ammonia and glutamate did not change immediately after infusions, but a 42% decrease in glutamine was observed. Eight nitrogen balance studies performed in five patients during 3-12 days of p.o. or i.v. keto acid therapy failed to show consistent improvement in balance as compared with control periods. After five courses of p.o. therapy, there was again significant improvement in the ratio of essential to nonessential amino acids. No toxicity from keto analogue administration was found, and clinical improvement, as assessed by mental status and psychological testing, occurred in 8 of 11 patients. These studies suggest keto analogues of essential amino acids are converted to the corresponding amino acids in patients with portal-systemic encephalopathy, and that such therapy may be beneficial.

5890 A DOG MODEL OF FULMINANT HEPATIC FAILURE PRODUCED BY PARACETAMOL ADMINISTRATION.

(Eng.) Gazzard, B. G.; Hughes, R. D.; Mellon, P. J.; Portmann, B.; Williams, R. (King's Coll. Hosp., London SE5, England). *Br. J. Exp. Pathol.* 56(5): 408-411; 1975.

In an attempt to produce an animal model of fulminant hepatic failure caused by paracetamol overdose, different doses of paracetamol were administered to dogs. All animals given 3 g/kg paracetamol (3 dogs) or 1 g/kg (6 dogs) p.o. became unconscious and cyanosed and died 6-31 hr later. All animals had elevated aspartate aminotransferase (65-8000 IU/l) and arterial ammonia (155-340 μM) levels within 6 hr after receiving the lower dose of paracetamol. Only one dog had extensive hepatic necrosis at autopsy, while the others showed normal livers or minor abnormalities. Two dogs given 0.25 or 0.5 g/kg paracetamol, i.p., did not lose consciousness, and showed no evidence of liver damage when they were sacrificed 5 days later. The dogs that received 0.75 or 1 g/kg, i.p., became unconscious and cyanosed. Methemoglobinemia was detected in the four dogs in which it was measured; the two animals in which methemoglobinemia formed over 40% of the total hemoglobin died rapidly. Methemoglobinemia was associated with a reduction in the arterial partial pressure of oxygen (<5 kPa). In one dog in which 25% of the hemoglobin was present as methemoglobin, methylene blue (1 mg/kg) caused a temporary increase in the arterial partial pressure of oxygen from 5 to 7 kPa and a decrease in the percentage of methemoglobin. The extent of the hepatic necrosis and the time of survival following paracetamol administration were too variable for this model to be valuable in testing of new methods of temporary liver support.

5891 MULTINODULAR HEPATIC HEMANGIOMATOSIS: ITS FAVORABLE COURSE IN EARLY CHILDHOOD.

(Fre.) Verger, P.; Guillard, J. M.; Fontan, D.; Laigle, J. L. (Hopital des Enfants, 168, cours Argonne, 33000 Bordeaux, France). *Med. Chir. Dig.* 3(5):347-352; 1974.

Multinodular hemangiomatosis, as illustrated by the case history of a 7-month-old infant and 44 other cases from the literature, is clinically characterized by cutaneous angiomata, hepatomegaly, and cardiac insufficiency. The diagnosis is very difficult in the absence of cutaneous angiomata. The disease is frequently fatal, especially during the first 6 months of life when the infant can develop fatal cardiac failure. Diagnostic procedures include blood studies, radiography, intravenous urography, celiac arteriography, angiocardiography, hepatic scintigraphy, and laparotomy. Therapy is symptomatic. Radiotherapy is known to be effective although it can lead to secondary cirrhosis. Corticotherapy has produced good results after failure with radiotherapy. Spontaneous recovery does occur as in the case reported.

5892 TREATMENT OF ACUTE HEPATIC INSUFFICIENCY BY EXTRACORPOREAL LIVER PERFUSIONS.

(Fre.) Lenriot, J. P. (Hopital de Longjumeau, 91 Longjumeau, France). *Med. Chir. Dig.* (Suppl. 2):43-48; 1975.

Liver perfusions from homologous and heterologous sources were used to treat 53 patients (aged 5-63 yr, 64% were women) in a stage IV coma as a result of acute hepatic insufficiency of infectious (43), toxic (8), or gravid (2) origin. A total of 83 perfusions, lasting 45 min to 51 hr, were performed, and repeated up to five times in some cases. Source of the perfusion was pork (36), calf (13), baboon (4), or human (3). Long-term recovery of hepatic function occurred in 7 patients, and 13 came out of the coma but died shortly thereafter, usually as a result of a complication of the hepatic insufficiency. The remaining 33 patients died without regaining consciousness. Failures of the hepatic perfusions were mostly methodological, such as immediate or rapid alterations of the perfused liver, immune reactions, or complications such as metabolic acidosis, hypoglycemia, respiratory distress, and septicemia. Therefore, extracorporeal perfusion with baboon liver appears to be one of the least harmful techniques for treatment of acute hepatic insufficiency. However, hemodialysis appears likely to replace the perfusion technique.

5893 LIVER DISEASE WITH PERIPORTAL SINUSOIDAL DILATATION. A POSSIBLE COMPLICATION TO CONTRACEPTIVE STEROIDS.

(Eng.) Winkler, K.; Poulsen, H. (Kommunehospitalet, Oster Farimagsgade 5, 1399 Copenhagen K, Denmark). *Scand. J. Gastroenterol.* 10(7):699-704; 1975.

The case reports of four women (aged 15-48 yr) who developed moderate liver damage and hepatomegaly after long-term treatment with oral contraceptives are presented. At the height of clinical illness, all patients had a marked elevation of ESR (66-130 mm/hr), together with a moderate increase in serum gamma globulins and a slight decrease in serum albumin. In two patients, serum bilirubin was moderately elevated (maximum value 3.0 and 3.6 mg/100 ml, resp.). Serum aspartate aminotransferases were normal in one case, and moderately elevated in the others, while serum alkaline phosphatases were slightly to moderately increased in all four patients. Prothrombin was normal in three cases, but low (6%) in one case; it increased to normal values following K vitamin therapy. Liver histology showed a conspicuous periportal sinusoidal dilatation as the only abnormality. The clinical course of the liver damage was benign. The etiology and pathogenic mechanisms of these changes, which were localized predominantly to Rappaport's Zone I, are unknown. Hemodynamic studies revealed no abnormalities. A relationship between the described changes in liver histology and any etiologic agent or known pathogenic mechanism cannot be established. Before the relationship between liver damage and hormone therapy can be determined, an insight into the metabolic fate of these hormones and the influence of their metabolism on cells in different parts of the liver is necessary.

5894 JAUNDICE IN PREGNANCY.

(Fre.) Lhonneux, C.; Barbier, P. (Hopital Universitaire Saint-Pierre, Brussels, Belgium). *Acta Gastroenterol. Belg.* 37(12):511-519; 1974.

Jaundice in pregnancy is reviewed. There are certain jaundices that occur almost exclusively during pregnancy, such as acute steatosis of Sheehan, recurrent jaundice usually caused by oral contraceptives, jaundice as a complication of pregnancy vomiting, jaundice of eclampsia, hepatic rupture, or severe antirhesus isoimmunization. Viral hepatitis is the most frequent cause of jaundice coincidental with pregnancy. It can affect the liver of the fetus as fetal contamination by the Australia antigen is observed in 47% of hepatic jaundices appearing between the 8th month of pregnancy and the 2nd postpartum month. Less frequent is the association of jaundice and liver cirrhosis because of the usual age of cirrhotic patients. Jaundice can be related to intrahepatic cholestasis as a result of drug toxicity or extrahepatic cholestasis caused by lithiases or edema of the pancreas.

5895 LIPID CONTENT IN THE LIVER OF FATTY METAMORPHOSIS OF PREGNANCY. (Eng.)

Eisele, J. W.; Barker, E. A.; Smuckler, E. A. (Dept. Pathology, Case Western Reserve Univ., Cleveland, OH 44106). *Am. J. Pathol.* 81(3):545-560; 1975.

The anatomic changes and lipid composition of the liver of a 29-yr-old patient who died from acute fatty liver of pregnancy are reviewed, and a comparison is made with livers from normal subjects and from subjects with nutritional fatty livers. An autopsy was performed within 1 hr of death. External examination revealed marked icterus and multiple petechiae. The peritoneal cavity contained 950 cm^3 of unclotted blood and a large hematoma involving the lower uterine segment, the broad ligaments, and the anterior abdominal wall. There was a bilateral bronchopneumonia, an erosive esophagitis, and multiple petechiae of the gastric and duodenal mucosa. Microscopically, the hepatic architecture was intact, although many of the lobules appeared shrunken. Occasional areas of focal cell loss consisting of hepatocellular dropout or eosinophilic necrosis were scattered through the lobules. The hepatocytes were distended, with small cytoplasmic vacuoles. There was an infiltration of neutrophils, lymphocytes, and macrophages. Bile pigment was present within hepatocytes, Kupffer cells, and some canaliculi. Small fat globules were also present in the cytoplasm of some of the renal proximal tubular cells, but fat was not detected in other organs. There were marked increases in free fatty acids in fatty liver of pregnancy (250 µmol lipid/g liver) and in triglycerides in nutritional fatty liver (220 µmol lipid/g liver). In neither instance could the change be the result of autolytic modification, since identical treatment of a normal liver was not associated with changes of similar magnitude. These results indicate that in fatty liver of pregnancy, the increase in hepatic lipids is in the form of free fatty acids. This contrasts with nutritional fatty liver, in which the increase is in the form of triglycerides.

5896 COPROPORPHYRIA: SEVEN CASES. (Fre.)

Jaeger, A.; Tempe, J. D.; Geisler, F.; Nordmann, Y.; Mantz, J. M. (Service de Reanimation medicale, Pavillon Pasteur, C.H.U., F 67000 Strasbourg Cedex, France). *Nouv. Presse Med.* 4(39):2783-2787; 1975.

Two cases of hereditary porphyria (44- and 38-yr-old women) with peripheral paralysis and severe respiratory failure are reported. While the outcome was fatal in one case (adenosine monophosphate was ineffective), the other patient slowly recovered although abdominal pains remained intermittent despite treatment with chlorpromazine and atropine. Two latent asymptomatic cases (2 of 8 children) were found in the family of the first patient (study of 12 of 30 members) and three diagnosed cases (father, sister, and brother) in the family of the second (8 members). The literature contains 86 cases of coproporphyria in a total of 25 families; only 32 individuals presented a clinical symptomatology while the others were carriers. Transmission of the disease is autosomal dominant. The expression of coproporphyria is weak as clinical signs in more than one member of a family have only been observed in six families. Hereditary porphyria resembles acute intermittent porphyria clinically although its biological characteristics are distinctive. Excretion of coproporphyrins in the urine and especially in the feces is massive while the excretion of porphobilinogen and delta-amino-levulinic acid is only slightly increased. Contrary to mixed porphyria, the fecal excretion of protoporphyrins is normal. Coproporphyria is usually benign but is sometimes fatal due to severe neurorespiratory complications. Treatment is symptomatic and preventative. Triggering factors, such as certain drugs (barbiturates, tranquilizers, anti-epileptics, estrogens, and antidepressors), must be avoided and latent carriers carefully sought in the families of affected individuals.

5897 MORPHOLOGICAL CHANGES IN THE LIVER AND ITS VESSELS IN SYSTEMIC SCLERODERMA.

(Rus.) Skorodumova, N. P. (Chair Pathology Anatomy, Donetsk Medical Inst., Donetsk, USSR). *Vrach. Delo* (4):34-39; 1975.

Thirteen of 25 patients with systemic scleroderma were found at autopsy to have had liver involvement. Liver tissues from these patients were examined by light microscopy to determine morphological changes and the clinical course of the disease. Liver enlargement was seen in a majority of cases; in two patients, the liver weighed 1,400-1,500 g; in five patients, it was 1,400-1,600 g; and in six patients, the liver weighed 1,900-2,400 g. Fibrosis of the portal tracts, perivascular fibrosis and sclerosis of the ducts, abundant mononuclear infiltration, and sometimes, cirrhosis were observed in the stroma. The parenchyma showed small- and large-drop fatty dystrophy, centrilobular necrosis, and hemorrhagic foci. Small and medium sized hepatic blood vessels showed sclerosis of the walls, in association with signs of disorganization (fibrinoid swelling, hyalinosis, and amyloidosis). Proliferative arteritis was seen in the hepatic artery.

Changes of the portal and hepatic veins were similar, and consisted of mild edema, defibering, and moderate sclerosis of the intima and adventitia.

5898 ANGIOGRAPHIC FINDINGS IN PRIMARY BILIARY HEPATIC TUBERCULOSIS. (Fre.) Remond, A.; Capron, J. P.; Henry, X.; Pietri, J.; Trinez, G. (C.H.U., F 80000 Amiens, France). *J. Radiol. Electrol. Med. Nucl.* 57(1):7-11; 1976.

Arteriography was used to diagnose primary micronodular hepatic tuberculosis in two men, aged 22 and 28 yr. Case reports including results of clinical studies, laparotomy, radiography, etc., reflect the difficulty of accurate diagnosis of the disease entity. Selective hepatic arteriography revealed normal anatomical distribution of the arteries; however, abnormalities appeared in the distal arterioles. Small, nodular, irregular formations were opacified encircling the arterioles. No abnormalities of the hepatic or portal veins were observed. Liver parenchyma in the vicinity of the arterioles appeared normal and homogeneous. Arteriography can distinguish micronodular tuberculosis from other hepatic pathologies, such as focal nodular hyperplasia, hemangioma, and neoplasm metastasis.

5899 HEPATIC VENO-OCCLUSIVE DISEASE: NOSOLOGY AND DIAGNOSTIC DIFFICULTIES. (Fre.) Barge, J.; Carbon, Cl.; Lamotte-Barrillon, S. (Laboratoire Central d'Anatomie Pathologique, Hopital Louis-Mourier, 178, rue des Renouillers, 92701 Colombes Cedex, France). *Sem. Hop. Paris* 52(16):1023-1025; 1976.

The case of a 42-yr-old man with chronic hepatic venoocclusive disease is reported. The cause of the symptoms of chronic liver disease was difficult to determine as the exterior of the liver appeared intact. Histological examination revealed extensive fibrosis of the hepatic venous system. Chronic hepatic venoocclusive disease should be suspected when no etiological factor can be found, and when a hepatic puncture biopsy does not reveal nodular regeneration (suggestive of an uncompensated cirrhosis). Identification of the venous lesions is not always possible because arteriography of the vena cava is difficult to interpret. The disease is usually rapidly fatal; the patient studied died of pulmonary embolism.

5900 TREATMENT OF ACUTE HEPATOCELLULAR INSUFFICIENCY BY CROSSED CIRCULATION WITH HUMANS OR BABOONS: TEN PERSONAL OBSERVATIONS. (Fre.) Muller, J. M.; Guignier, M.; Guillaud, J. LIVER AND BILIARY TRACT

Hyperbilirubinemic States

5927 GILBERT'S SYNDROME: RECENT DATA ON CLINICAL AND DIAGNOSTIC ASPECTS AND ON THE THERAPEUTIC APPROACH. (Ita.) Okolicsanyi, L.; Cortelazzo, S.; Orlando, R.; Benedetti, G.; Naccarato, R. (Istituto di Patologia speziale medica e metodologia clinica, Universita, Padova, Italy). *Recent. Prog. Med. (Roma)* 58(5):560-593; 1975.

Clinical, diagnostic, and therapeutic data on Gilbert's syndrome are reviewed. When exogenous bilirubin is administered i.v., a net deficit in pigment uptake is observed, even in cases where the plasma clearance of BSP is normal; such a deficit may be responsible for hyperbilirubinemia. A net decrease in the conjugation-excretion process of bile pigment is also observed in Gilbert's syndrome. The existence of a deficit in glucuronyl transferase is now accepted; this deficit is especially evident when the enzyme's activity is tested with bilirubin as the natural substrate. Two mechanisms that may be responsible for the hyperbilirubinemia in Gilbert's syndrome, an uptake deficit and a conjugation deficit, are thus confirmed.

5928 GILBERT'S SYNDROME. ACTION OF URIDINE DIPHOSPHATE GLUCOSE ON BILIRUBIN METABOLISM. (Fre.) Ventura, E.; Zeneroli, M. L. (Istituto di Clinica medica Geverde e Terapia medica dell'Universita di Modena, Modena, Italy). *Med. Chir. Dig.* 4(5/6):283-286; 1975.

Six patients with Gilbert's syndrome received uridine diphosphate glucose (UDPG), 100 mg, i.v. for 7 days. Plasma clearance and transfer of bilirubin into the microsomal compartment of the liver cell were measured after 2 mg/kg, i.v., of bilirubinic acid was administered 3 days before and 7 days after UDPG treatment was initiated. UDPG apparently increases glucuronoconjugation of bilirubin since the amount of bilirubin in the microsomal compartment of the hepatocytes increased significantly. A graph of plasma clearance of bilirubin after 7 days of UDPG treatment showed lower plasma levels, particularly from 1-4 hr, compared to the basal study. UDPG did not modify bilirubin uptake or hepatoplasma reflux. The results suggest that UDPG may be beneficial in the treatment of Gilbert's syndrome.

5929 STUDY OF THE KINETICS OF BILIRUBIN IN A CASE OF DUBIN-JOHNSON'S SYNDROME BEFORE AND AFTER TREATMENT WITH UDPG. (Ita.) Orlando, R.; Caregaro, L.; Muggeo, M.; Ghidini, O.; Okolicsanyi, L. (Istituto di Patologia Speciale Medica dell'Universita di Padova, Padova, Italy). *Clin. Ter.* 76(4):323-382; 1976.

A 47-yr-old patient with Dubin-Johnson syndrome was treated with uridine diphosphate glucose (UDPG, 80 mg/day, i.m., for 10 days). Plasma bilirubin clearance significantly accelerated. Passage of unconjugated bilirubin from the plasma to the hepatocytes increased, as did the intrahepatocytic passage of bilirubin from the compartment of unconjugated pigment to that of conjugated pigment. Reflux rate from the hepatocytes to the blood decreased. Total bilirubinemia was the same (2.43 mg%) before and after initial treatment; however, another 2 weeks of treatment lowered the levels to 1.19 mg%. Jaundice was attenuated. The results probably represent an activation of the postmicrosomial transport systems, perhaps through improved glycogen synthesis. However, a concomitant action of UDPG on the hepatocytic membrane should not be excluded.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

5932 AZATHIOPRINE-INDUCED INTRAHEPATIC CHOLESTASIS. (Ger.) Iselin, H.; Knoblauch, M.; Binswanger, U.; Spycher, M.; Ruttner, J.; Staubli, M.; Lammli, J.; Frey, P. (Departement fur Innere Medizin, Universitat Zurich, Zurich, Switzerland). *Schweiz. Med. Wochenschr.* 106(9):320-321; 1976.

Azathioprine-induced cholestasis was observed in 4 of 300 renal transplant patients. It was manifested by slowly developing, nonpainful icterus, without substantial impairment of the general condition and without systemic hypersensitivity reactions. All patients were receiving prednisone (10 mg/day) in addition to azathioprine. In some cases, maximum elevations of alkaline phosphatase, cholestatic enzymes, LAP, and 5-nucleosidase values were not reached until several weeks after azathioprine was stopped. Hepatitis B antigen was negative on repeated tests in all four patients, and there were no antibodies against DNA, cell nuclei, or smooth musculature. Antimitochondrial antibodies were present in one case. The histological picture was highly variable. Acute transplant rejection did not occur. The time interval between transplant and occurrence of cholestasis was not correlated with the total quantity of azathioprine administered nor with its average dose. Other possible causes of liver damage were eliminated, except in one patient who had had hepatitis 1 yr earlier. Hyperbilirubinemia disappeared completely within a few weeks after replacement of azathioprine by cyclophosphamide. Normalization of transaminases and cholestatic enzymes took several months in some of the cases.

5933 THE USE OF (+)-CATECHIN IN THE THERAPY OF HEPATIC DYSFUNCTION IN THE COURSE OF ANTITUBERCULAR THERAPY. PRELIMINARY RESULTS.

(Eng.) Grassi, C.; Casali, L. *In: New Trends in the Therapy of Liver Diseases. Proceedings of the International Symposium on New Trends in the Therapy of Liver Diseases, Tirrenia, June 6-7, 1974.* (Basel: Karger): pp. 191-198; 1975.

The use of (+)-catechin for the treatment of hepatic dysfunction was studied in 10 tuberculous men undergoing antituberculous treatment. (+)-Catechin was given at a total daily dosage of 1,500 mg, divided into three doses before meals for 30 days. Best results were obtained in patients in whom a fatty degeneration of hepatocytes was present. A clear tendency to normalization was noted in patients with dyspepsia. Transaminase values improved, but the 4-week study was too short for them to reach normal levels. In seven patients, bilirubin and alkaline phosphatase normalized. BSP retention values were excellent in four patients, and a notable improvement was seen in two others. In the three patients affected by cirrhosis, BSP retention studies showed unsatisfactory results. A certain degree of improvement in liver function tests can be achieved by (+)-catechin treatment. Clinically, an objective improvement was noted in most patients, particularly a clear-cut regression of the dyspeptic syndrome (8 of 10), an increased appetite (10 of 10), and a decreased jaundice (4 of 6; 4 patients has no jaundice). No side effects of the treatment were noted.

5934 HEPATOTOXIC HAZARD OF RIFAMYCIN.

(Fre.) Emerit, J. (Hopital de la Salpetriere, 47, bd de l'Hopital, 75634 Paris Cedex 13, France). *Entretiens Bichat. Ther.* 1975:140-142.

The hepatotoxic effect of rifamycin is enhanced by its combination with another substance metabolized by the liver, such as isoniazid. These drugs are involved in enzymatic competitive binding, adaptation, or inhibition processes; this can lead to an accumulation of the drugs' metabolites or radicals and to hepatic necrosis. The risk of hepatic toxicity will be greater when several drugs such as anticoagulants, phenylbutazone, sulfamides, and hypoglycemic agents are administered concomitantly. It will also be increased by the presence of a hepatic lesion or a deficient nutritional state.

5935 A CASE OF HEPATIC MUCORMYCOSIS.

(Fre.) Chailly, P.; Couturier, E. (Hopital Universitaire St.-Pierre, Bruxelles, Belgium). *Brux. Med.* 55(6):327-330; 1975.

A rare case of mucormycoses with liver involvement is reported in a 31-yr-old man. Initially hospitalized for an aplastic anemia attributed to a drug reaction, the patient was treated with blood transfusions and 500 mg/week of testosterone. He was hospitalized again for bronchopneumonia with pleural effusion. Blood and pleural fluid remained negative for pathogens; however, when the patient was treated with lincomycin and gentiamycin the signs of pneumonia regressed. Shortly thereafter, the clinical picture suggested a subphrenic abscess. The liver was enlarged and tender, and angiography suggested two intrahepatic abscesses. Surgical intervention revealed hepatic necrosis. Culture of the necrotic tissue was negative. The patient developed symptoms of hepatic insufficiency and died. The diagnosis of disseminated mucormycoses was made after histological examination of organs removed at autopsy. The fungal infection involved the lung, liver, spleen, and was the cause of a subhepatic thrombosis.

5936 FULMINANT HEPATITIS DUE TO THE "GLUE THISTLE" (Atractylis gummifera L): AN ANATOMIC-PATHOLOGIC STUDY OF FOUR CASES.

(Fre.) Lemaigre, G.; Tebbi, Z.; Galinsky, R.; Michowitcz, S.; Abelanet, R. (Service central d'Anatomie pathologique, C.H.U. Ben Badis, Constantine, Algeria). *Nouv. Presse Med.* 4(40):2865-2868; 1975.

Ten cases (children) of fulminant hepatitis with major hepatocytic necrosis due to the consumption of *Atractylis gummifera L* are reported. Four patients died at home. Of the six hospitalized children, only two survived. Autopsies of four children revealed extensive necrosis of the hepatic parenchyma, and congested centrilobular veins with edemous parietal thickening and endothelial necrosis. The mucosa of the small intestine displayed notable capillary congestion, and the renal parenchyma displayed tubulonephritic lesions of toxic origin. Clinical symptoms, which appeared within 24 hr of consumption, consisted of headache, epigastric pain, vomiting, rapidly followed by deep coma, major neurovegetative disorders (tachycardia, hypothermia), and sometimes digestive hemorrhage. The main toxic agent, potassium atractylate, competes with ADP by preventing its transformation into ATP in the mitochondria, and inhibits glycogen synthesis and oxidative phosphorylation.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

5941 THE PREVENTION OF HEPATITIS A USING POLYVALENT IMMUNOGLOBULINS. (Fre.) Celers, J.; De Romeuf, J.; Breart, G.; Bingino, C.; Dethan, M. (Sous-Direction de l'Hygiene Publique, 20 bis rue d'Estrees, F 75007 Paris, France). *Nouv. Presse Med.* 5(3):129-132; 1976.

The effectiveness of polyvalent immunoglobulins (Ig) for the treatment of hepatitis A was determined in a longitudinal study of a residential center for children with primary tuberculosis. Fifty children (under 10 yr of age) and 17 young adults (17- to 20-yr old), exposed to endemic hepatitis A, received Ig every 3 months for 1-17 months. Polyvalent Ig from human plasma was injected at doses of 0.1-0.2 ml/kg for children and 10 ml/kg for young adults (in a 16.5% solution). Sixty children and 30 young adults served as controls. SGPT levels increased in 6 of 30 control adults with icteric viral hepatitis but in none of those treated adults. SGPT levels also increased in 16 of 50 treated children, and in 31 of 60 control children. Viral contamination preceded treatment in 5 of 16 treated children because biological symptoms appeared less than 20 days after hospital admission. The remaining 11 developed symptoms 20-339 days later, which suggests hospital contamination. Although not foolproof, Ig treatment will prevent hepatitis A in 80-90% of cases when administered less than 14 days after contamination or before contamination.

5942 NONHUMAN PRIMATE-ASSOCIATED VIRAL HEPATITIS TYPE A: SEROLOGIC EVIDENCE OF HEPATITIS A VIRUS INFECTION. (Eng.) Dienstag, J. L.; Davenport, F. M.; McCollum, R. W.; Hennessy, A. V.; Klatskin, G.; Purcell, R. H. (Natl. Inst. Allergy Infectious Diseases, Natl. Inst. Health, Bldg. 7, Room 301, Bethesda, MD 20014). *JAMA* 236(5):462-464; 1976.

Paired serum samples from two hepatitis outbreaks were tested for antibody to hepatitis A antigen (anti-HA) by immune adherence hemagglutination (IAHA) to determine whether two previously reported cases of nonhuman primate-associated viral hepatitis (NPAH) were caused by human viral hepatitis type A. In 1964, five cases of NPAH were identified among contacts of a recently imported chimpanzee in Wayne County, MI. Among three individuals tested, serological evidence showed acute infection with hepatitis A virus. Sera were negative for the hepatitis B surface antigen (HBsAg), and no serological response was found to either of the two antigens associated with hepatitis B virus. In 1970, eight cases of NPAH were identified among contacts of a chimpanzee in Bridgeport, CT. A liver biopsy of the chimpanzee showed morphological changes consistent with mild, resolving acute hepatitis. A woolly monkey gave chemical and histological evidence of acute hepatitis at the same time. The woolly monkey did not have contact with the chimpanzee, but was handled by the same animal handlers. In a cage mate of the chimpanzee, acute infection was documented serologically by high titer antibody development, despite the absence of clinical signs of disease. One handler had a serologic response consistent with acute infection. Both the woolly monkey and its cage mate (which had an inapparent infection) seroconverted, and anti-HA developed. All affected animals and humans were free of serum HBsAg, and no rising titers of serum anti-HBs or antibody to the hepatitis B core antigen developed in these cases. This is the first demonstration of susceptibility to hepatitis A virus infection in woolly monkeys. This study confirms retrospectively by serologic means an association between hepatitis A virus and NPAH in two outbreaks, widely separated by time and place.

5943 (+)-CYANIDANOL-3 TREATMENT IN ACUTE VIRAL HEPATITIS. (Eng.) Seyfried, H.; Brunner, H.; Grabner, G. *In: New Trends in the Therapy of Liver Diseases. Proceedings of the International Symposium on New Trends in the Therapy of Liver Diseases, Tirrenia, June 6-7, 1974.* (Basel: Karger): pp. 177-181; 1975.

The clinical effects of (+)-cyanidanol-3 were studied in 35 patients with acute viral hepatitis. Eighteen patients received 0.5 g of (+)-cyanidanol-3 three times daily, and 17 patients received a placebo. There were no significant differences between the two groups with respect to age; sex ratio; time elapsed between the initial symptoms and hospitalization; initial values for total serum bilirubin, SGOT, and SGPT; and the duration of hospitalization. Since the patients were hospitalized at different stages of their illness, an attempt was made to adjust all cases to the same stage of disease by using peak bilirubin and transaminase levels as point of comparison. The time it took for serum bilirubin levels to fall from 10 mg% to 2 mg%, and for transaminase levels to fall from their initial elevated values to 100 mU/ml was calculated. The serum bilirubin fell more rapidly in the patients receiving therapy than in the controls; in treated patients, the level fell from 10 to 2 mg% on an average of 5 days earlier than in controls. Similarly, a more rapid decline in transaminase levels was seen in treated patients; the mean number of days required for SGOT and SGPT levels to fall to 100 mU/ml was 5.3 and 9.1, resp., in the treated patients, and 10.2 and 13.1 days, resp., in the controls. The results show that (+)-cyanidanol-3 treatment does not influence the length of hospitalization nor the period from admission to the final disappearance of hyperbilirubinemia. When the results are adjusted to the same stage of disease, it appears that (+)-cyanidanol-3 treatment may be effective during the healing phase of uncomplicated acute viral hepatitis by accelerating the decrease of biochemical substances that are considered to be signs of cellular damage.

5944 HEMATOLOGIC MANIFESTATIONS OF COMMON ACUTE VIRAL HEPATITIS. (Fre.) Chivrac, D.; Capron, J.-P.; Lorriaux, A. (Centre Hospitalier Universitaire, place Victor-Pauchet, F 80030 Amiens Cedex, France). *Arch. Fr. Mal. App. Dig.* 65(3): 239-248; 1976.

A literature review is presented of hematologic changes observed in the course of acute viral hepatitis. Erythrocytic alterations consist of higher hemoglobin and hematocrit values at the start of icterus than at the end (within normal limits); this variation may be caused either by an initial erythrocytosis or a late anemia. The most frequent leukocytic anomaly is early leukopenia; less frequent are a relative or absolute lymphocytosis, hypereosinophilia, and hyperleukocytosis. Leukopenia is due to a transitory medullary insufficiency, perhaps related to the multiplication of the virus in the hematopoietic organs. Blood platelet count is hardly modified. Posthepatic medullary aplasia occurs rarely, but is irreversible and usually fatal (mortality, 85.1-88%). There is an average of 9.3 weeks between the beginning of the hepatitis and the onset of the aplasia. The causal mechanism may be related to hepatocellular insufficiency, an autoimmune mechanism of viral origin or, most likely, the medullary toxicity of the virus. Hypersensitivity of some individuals and toxic drug reactions have also been implicated in the development of medullary aplasia.

5945 THE NUCLEAR DRY WEIGHT OF LIVER CELLS FROM PATIENTS WITH VIRUS HEPATITIS AND FROM CONTROLS. (Eng.) Ranek, L. (Div. Hepatology Rigshospitalet, Copenhagen 0, Denmark). *Acta Cytol. (Baltimore)* 20(1):58-61; 1976.

Experiments were carried out in hepatic biopsy material from 11 patients with viral hepatitis and from 7 patients with normal livers, to determine whether increased nuclear dry weight of liver cells is responsible for the higher nuclear volume seen in patients with viral hepatitis. The nuclear dry weights were determined by microinterferometry. The average nuclear dry weight of diploid nuclei was significantly greater in patients with hepatitis (45.4 pg) than in controls (39.9 pg). The average nuclear volume of diploid nuclei was 241 μ^3 in controls and 274 μ^3 in the hepatitis patients, which was not statistically significant. The average volume of tetraploid nuclei was 492 in controls and 525 in hepatitis patients. The average dry mass concentration was not significantly different, neither between controls and hepatitis nuclei nor between di- and tetraploid nuclei. The correlation coefficients between dry weight and volume of diploid nuclei were significantly positive in all but one of the hepatitis cases; in it, the correlation was 0.381. The results show that during viral hepatitis the nuclear dry weight and volume increase. It appears that the increased nuclear dry weight of liver cells is responsible for the higher nuclear volume seen in patients with viral hepatitis.

5946 PECULIAR ASPECTS ("VIROPLASMS") OF VIRAL TYPE PARTICLES WITHIN THE HEPATOCYTES IN HEPATITIS WITH AUSTRALIA ANTIGEN. (Fre.) Leung, T. K.; Feroldi, J.; Bertrand; Bonnamour, C.; Brette, R. (Laboratoire d'Anatomie pathologique, Universite Claude Bernard, 8, avenue Rockefeller, 69373 Lyon Cedex 2, France). *Ann. Anat. Pathol.* 20(3): 293-302; 1975.

Intrahepatocytic particles were observed ultrastructurally in liver biopsies of 32/45 patients with hepatitis positive for the Australia antigen. Contrary to the usual viral particles associated with the Australia antigen, these particles were dense, granulofilamentous agglomerates, dispersed in the nucleus, sometimes in the immediate vicinity of the nucleoli and nuclear bodies. Within the agglomerates, complete or partial rounded particles were observed, the morphology of which was reminiscent of the usual intranuclear particles. In view of the accepted chronology of viral replication, these agglomerates can be referred to as "viroplasms" and are representative of an intermediate stage in the formation of nuclear particles. The data support the hypothesis that nuclear replication of the particles is associated with the Australia antigen.

5947 LOCALIZATION OF HEPATITIS B SURFACE ANTIGEN IN CONVENTIONAL PARAFFIN SECTIONS OF THE LIVER. COMPARISON OF IMMUNOFLUORESCENCE, IMMUNOPEROXIDASE, AND ORCEIN STAINING METHODS WITH REGARD TO THEIR SPECIFICITY AND RELIABILITY AS ANTIGEN MARKER. (Eng.) Nayak, N. C.; Sachdeva, R. (All-India Inst. Medical Sciences, Ansari Nagar, New Delhi-110016, India). *Am. J. Pathol.* 81(3):479-492; 1975.

Immunofluorescence, immunoperoxidase, and orcein staining methods were compared for their specificity and reliability as a marker for hepatitis B antigen (HBAg). Six consecutive sections were cut from paraffin blocks of formalin-fixed liver tissue collected at autopsy from 43 subjects with various liver diseases. Slide 1 was stained by hematoxylin and eosin, and the remaining slides were stained for HBAg by various procedures. Antigen was observed in the livers from several patients with cirrhosis and primary liver cancer, but in none of the other livers, including one from a patient with acute fulminant hepatitis. Whenever a HBAg-positive liver was identified, localization could generally be uniformly seen by all staining techniques. Immunoperoxidase staining by either the double or single sandwich technique presented a much more convincing localization of the antigen than immunofluorescence or orcein; assessment was much easier than in the immunofluorescent preparation, and comparison with the orcein-stained material was considerably simpler. Localization in orcein-stained preparations, both within individual cells and in geographic areas of the tissue section, matched extremely well with that seen in the immunofluorescence and immunoperoxidase preparations. The morphology and structure of HBAg was most evident in the orcein-stained preparations, and to a large extent in the immunoperoxidase preparations. In the orcein stain, the amber staining of the antigen stood out prominently against the beige cytoplasmic background, and the hematoxylin staining of the nucleus. The results demonstrate that HBAg can be clearly localized in the liver cells of formalin-fixed, paraffin-embedded material. Localization can be successfully achieved, not only by empirical orcein staining, but also by the specific immunostaining methods using fluorescence and peroxidase.

5948 GENOME OF HEPATITIS B VIRUS: RESTRICTION ENZYME CLEAVAGE AND STRUCTURE OF DNA EXTRACTED FROM DANE PARTICLES. (Eng.) Summers, J.; O'Connell, A.; Millman, I. (Inst. Cancer Res., Fox Chase Cancer Center, Philadelphia, PA 19111). *Proc. Natl. Acad. Sci. USA.* 72(11):4597-4601; 1975.

The structure of unreacted DNA from Dane particles was characterized by specific cleavage with a restriction enzyme from *Hemophilus aegyptius* (R-HaeIII) and by gel electrophoresis. *In vitro* replicated DNA from Dane particles was resolved into two components by polyacrylamide gel electrophoresis: the major component migrated at a position of linear DNA of 3,600 nucleotide pairs; the other was heterogeneous in size, and migrated at positions ranging from less than 1,500 to approximately 3,600 nucleotide pairs. *In vitro* replication of undenatured DNA using avian myeloblastosis virus DNA polymerase and [α-^{32}P]dATP indicated the presence of substantial single-stranded regions in the molecule. The native DNA migrating through the gel separated into two components typical of the behavior of linear and circular double-stranded DNA of the same molecular weight. The faster form migrated like double-stranded linear DNA 3,600 nucleotides in length; the slower form appeared to be a circular form 3,600 nucleotides in length. Both forms migrated more rapidly if they were obtained early in the reaction, indicating that single-stranded regions were being repaired. The radioactive product at the end of the reaction was approximately 3,600 nucleotides in length, but at earlier times, radioactivity appeared in molecules less than 3,600 nucleotides in length, indicating that elongation of shorter strands occurred during the course of the reaction. It is concluded that the Dane particle DNA is a double-stranded circular DNA approximately 3,600 nucleotides in length, containing a single-stranded gap of 600-2,100 nucleotides. Although the Dane particle DNA may code for the virion DNA polymerase, the specificity of the reaction appears to reside in the template DNA and not in the DNA polymerase.

5949 DISTRIBUTION PATTERN OF ISOENZYMES OF ALKALINE PHOSPHATASE IN PATIENTS WITH VARIOUS FORMS OF HEPATITIS. (Ger.) Ohlen, J.; Richter, J. (II. Medizinische Klinik und Poliklinik der TU, Ismaninger Strasse 22, D-8000 Munich 80, W. Germany). *Med. Klin.* 71(7):292-299; 1976.

The hypothesis that the elevated alkaline phosphatase (AP) levels in various types of hepatitis correspond to different isoenzyme compositions, depending on whether the AP accumulation is due to uniformly impaired degradation of the intestinal, osseous, and hepatobiliary components or to a combination of this with hepatobiliary reflux, was examined. Measurements were made weekly for 2-3 months in 40 patients with uncomplicated acute hepatitis, 12 patients with cholestatic hepatitis, and 10 patients with histologically confirmed chronic persistent hepatitis. The isoenzyme distribution pattern in acute hepatitis corresponded qualitatively to that of the control group throughout the course of the disease. The fraction of intestinal AP remained close to the control value of 20%. The Q-value, reflecting the ratio of hepatobiliary to osseous enzyme, also remained close to the control value of 17. In cholestatic hepatitis, the share of AP declined to about 13% at 3-6 weeks, then increased to 18% by 8 weeks. The Q-value rose to 31 during the first week, then declined as the illness resolved, reaching 21 by 8 weeks. In the patients with chronic persistent hepatitis, the percentage of intestinal AP remained slightly, but significantly, elevated throughout 12 weeks of observation, while the Q-value varied only slightly. The hypothesis that the correspondance of the AP elevation to isoenzyme composition depends on the impaired degradation of the intestinal, osseous, and hepatobiliary components and to hepatobiliary reflux was confirmed.

5950 ISOENZYMATIC SPECTRUM OF LACTATE DEHYDROGENASE, MALATE DEHYDROGENASE, ALDOLASE AND ASPARTATE AMINOTRANSFERASE IN INFECTIOUS HEPATITIS (BOTKIN'S DISEASE).

(Rus.) Tkemaladze, L. M.; Pirtskhalava, M. B. (Inst. Experimental Clinical Therapy, Ministry Public Health, Georgia, USSR). *Ter. Arkh.* 46(4):59-62; 1974.

The isoenzymatic spectrum of lactate dehydrogenase (LDH), malate dehydrogenase (MDH), aldolase, and aspartate aminotransferase in infectious hepatitis and its dynamics were studied using the enzymograms of 60 patients. Isoenzymes were determined by disc electrophoresis in polyacrylamide gels. Considerable shifts in isoenzymes were seen in the spectra of LDH, MDH, aldolase, and aspartate aminotransferase. The content of the cathode fractions increased, but that of the anode fractions decreased. In the spectrum of LDH, the content of LDH-4 increased, and that of LDH-5 was sharply increased. Among the isoenzymes of MDH, the sharp increase in MDH-3 was still less than that of MDH-5. The content of aldolase-4 and aldolase-5 was increased, as was the activity of mitochondrial aspartate aminotransferase. Despite the reduction of total activity in these enzymes over the patients' hospitalization, no normalization of enzymograms was observed.

5951 STUDIES OF THE "e" ANTIGEN IN ACUTE AND CHRONIC HEPATITIS.

(Eng.) Smith, J. L.; Murphy, B. L.; Auslander, M. O.; Maynard, J. E.; Schalm, S. S.; Summerskill, W. H. J.; Gitnick, G. L. (Center Disease Control, Phoenix, AZ). *Gastroenterology* 71(2):208-209; 1976.

The sera of 32 healthy hepatitis B surface antigen (HBsAg)-negative patients, 24 healthy HBsAg carriers, 76 patients with post-transfusion hepatitis, and 50 patients with chronic active liver disease (CALD) were tested for the presence of e antigen and e antibody by rheophoresis, to assess the clinical significance of these serological markers in acute and chronic hepatitis. Among the 50 patients with CALD, 18 had a serologically documented, antecedent hepatitis B infection, and the remaining cases were serologically proven to be unrelated to hepatitis B. The e antigen or antibody was found only in patients with serological evidence of past or current hepatitis B virus infection. Whereas e antibody was found both in patients with HBsAg and with antibody to HBsAg (anti-HBs), e antigen was detected only in sera positive for HBsAg. The antigen was found in 8 of 15 HBsAg-positive CALD patients, compared with 2 of 24 asymptomatic HBsAg carriers. E antibody was found in 15 of 24 asymptomatic HBsAg carriers, in comparison with only 3 of 18 CALD patients with antecedent hepatitis B infection. Of the three anti-e-positive CALD patients, two were anti-HBs-positive and one was HBsAg-positive. The two patients whose acute phase sera contained e antigen were not the same as two patients whose convalescent phase sera contained e antibodies. The data confirm the specific association between the e determinant and hepatitis B infections, and indicate that e antigen is closely associated with evidence of chronic hepatic dysfunction, in contrast to the association of e antibody with hepatic normalcy in HBsAg carriers. These correlations are not absolute, and it should not be inferred that all e antigen-positive individuals will develop chronic hepatitis or that the presence of e antibody invariably protects against the development of chronic hepatitis.

5952 TRANSMISSION OF HEPATITIS TYPE B FROM HEALTHY HBsAg-POSITIVE MOTHERS.

(Eng.) Skinhoj, P.; Cohn, J.; Bradburne, A. F. (Bispebjerg Hosp., DK-2400 Copenhagen NV, Denmark). *Br. Med. J.* 1(6000):10-11; 1976.

Sera from 17 mothers, all apparently healthy carriers of hepatitis B surface antigen (HBsAg), were tested for HBsAg, the HBsAg antibody (anti-HBs), hepatitis B core antigen (HBcAg), and heaptitis B-associated e antigen (HBeAg) for 4-5 yr. The transmission rate of hepatitis B virus (HBV) infection to the children during pregnancy was determined. The subjects included 16 index children who showed no evidence of transmission 1 yr after birth, 16 mothers, 13 additional siblings (aged 18 months-8 yr), and 5 husbands. The 17th index mother had had a renal graft; she, her 3-yr-old child, and her husband were also included. At the follow-up examination, all mothers were asymptomatic and had circulating antibodies to HBcAg. HBeAg was found only in the renal transplant recipient, while the other 16 mothers had antibodies to the e determinant. All children of these 16 mothers had normal liver function and remained negative for HBsAg and anti-HBs. Anti-HBc was found in three children from different families. None of the fathers showed evidence of infection. The child of the HBeAg-positive mother was positive for HBsAg, HBeAg, and anti-HBc and had a slightly raised alanine aminotransferase level. The father had no history or evidence of infection, but he was positive for anti-HBs, and his alanine aminotransferase level was elevated. A second child, born near the end of the study period, became positive for HBsAg despite prophylactic hyperimmune γ-globulin treatment at birth. This study confirms that the healthy HBsAg carriers, although positive for anti-HBc, did not infect their children during the 4-5 yr study. In contrast, hepatitis was transmitted to the children and husband of the HBeAg-positive mother.

5953 HEPATITIS B IN AUSTRALIAN ABORIGINES AND TORRES STRAIT ISLANDERS: GEOGRAPHICAL, AGE, AND FAMILIAL DISTRIBUTION OF ANTIGEN SUBTYPES AND ANTIBODY. (Eng.) Barrett, E. J. (Queensland Inst. Medical Res., Herston Rd., Valley, Queensland 4006, Brisbane, Australia). *Aust. N.Z. J. Med.* 6(2):106-111; 1976.

The high rate of hepatitis B antigenemia was studied in Australian aborigines, using serum samples from the Northern Territory and Queensland. Immunodiffusion showed that populations from 16 centers in the Northern Territory had an overall incidence of 8.5%, in contrast to 2.7% in Queensland. Subtype *ay* predominated in both areas. The *d* antigen was not found in these areas, and only subtype *ad* was found in Torres Strait Island adults. Both the *d* and *ad* subtypes were found in Brisbane hepatitis patients and blood donors. In the Northern Territories, reactors were more frequent among males ($0.025<p<0.01$) and in younger age groups ($p<0.001$). In Queensland, reactors were more frequent among males, but less frequent in persons under 30 yr ($0.05<p<0.025$). Four of 213 sera tested were negative by immunodiffusion, but positive by complement fixation, although only at a titer of 1 in 8. Forty-nine of the 213 were anticomplementary; an additional reactor was found among 133 aboriginal children (0.8%). A higher proportion of additional reactors occurred among three adult groups: 6 of 39 Australian aborigines from Kowanyama, 1 of 10 from Aurukun, and 9 of 40 from Torres Strait gave reactions which could be inhibited specifically by antiserum. Antibody reacting by passive hemagglutination to reciprocal titers of 16 or more was prevalent in Australian aborigines (46/662, 6.9%) and Torres Strait Islanders (6/58, 10.3%) but was uncommon in Caucasians (1/234, 0.4%). Antibody prevalence increased with age in aborigines, and positive reactors were distributed throughout the population with less evidence of clustering. It is concluded that the high prevalence of hepatitis B antigen and antibody in these populations indicates a much higher incidence of infection than has been found in urban Caucasian populations.

5954 HEPATITIS B IN RETREAT FROM DIALYSIS UNITS IN UNITED KINGDOM IN 1973. PUBLIC HEALTH LABORATORY SERVICE SURVEY. (Eng.) Polakoff, S.; *et al.* (Central Public Health Lab., London NW9 5HT, England). *Br. Med. J.* 1(6025):1579-1581; 1976.

A survey of the incidence of hepatitis in hemodialysis units that began in 1968 was combined in January 1970 with a hepatitis B prevention program; the results obtained from 33 of the 48 hemodialysis and transplant units in the United Kingdom in 1973 are presented. The hepatitis B prevention program is based on regular tests for hepatitis B surface antigen (HBsAg) of sera from patients and staff before entry to the units and at regular intervals afterwards. Since the institution of this program, there had been a sustained decline in the incidence of hepatitis B, to the low level of 0.3% among patients and 0.1% among staff members in 1973. The infection developed in only three patients, who were all in one unit in which a hepatitis B outbreak had been in progress since 1970. Two staff members in the same unit developed the disease. The incidence of other types of hepatitis among patients was higher in 1973 than in the previous peak year, 1970. Of the 1,913 patients being maintained in the 33 units, 33 were HBsAg carriers in 1973, and a further 8 patients (not tested in 1973) had been persistent carriers previously; if these eight are assumed to have continued HBsAg carriage, the prevalence of HBsAg among all patients in 1973 was 2.1 per 100. Comparisons with data from other countries suggest that the almost complete elimination of hepatitis B from dialysis units in the U.K. was due to the prevention program.

5955 OYSTER-ASSOCIATED HEPATITIS: LESSONS FROM THE LOUISIANA EXPERIENCE. (Eng.) Mackowiak, P. A.; Caraway, C. T.; Portnoy, B. L. (Dallas Veterans Admin. Hosp., 4500 S. Lancaster Rd., Dallas, TX 75216). *Am. J. Epidemiol.* 103(2):181-191; 1976.

An outbreak of oyster-associated hepatitis, which occurred in Louisiana during October and November of 1973, is related to two similar outbreaks, which occurred simultaneously in Houston, Texas and Calhoun, Georgia. All of the infected persons had consumed raw oysters: 263 had eaten them in one of 10 Houston restaurants; 15 of 225 persons attending one of two dinners in Calhoun were infected; and 37 persons from Louisiana were infected. Contamination of the oysters probably occurred before harvesting, and probably during Mississippi River flooding the previous spring. The oysters concentrated the virus in their tissue, to a level in excess of that which existed in the surrounding waters. They retained the virus for 1-2 months after the flood receeded. Because these waters were closed after the flooding, no oysters reached consumers until the last week of August. Given the 1-month incubation period for hepatitis A, it is not surprising that cases of hepatitis were not noted until early October.

5956 THE HEPATITIS B ANTIGEN IN CHRONIC GLOMERULONEPHRITIS. (Fre.) Guardia, J.; Pedreira, J. D.; Martinez-Vazquez, J. M.; Vidal, M. T.; Vilardell, M.; Caralps, A.; Ferrer, E.; Bacardi, R. (Departements de Medecine Interne et Pathologie, Cite Sanitaire de la Securite Sociale, Universidad Autonoma, Barcelona 16, Spain). *Nouv. Presse Med.* 4(41):2923-2925; 1975.

The association of glomerulonephritis with the hepatitis B antigen (HBAg) and chronic hepatitis was studied in 11 cases of chronic glomerulonephritis (5 membranous forms, 3 mesangial, 2 membranoproliferative, and 1 endo- and extracapillary with hyaline thrombus). Serum was positive for HBAg in eight cases and anti-HBAg was present in one case. In the first group, six patients had subtype *ad* and two, subtype *ay*. Three relatives from two families were also HBAg-positive, with the same subtype as the patient. Hepatic biopsy of six patients revealed three with active chronic hepatitis, two with persistant chronic hepatitis, and one patient without hepatitis (patient with anti-HBAg). The data suggest that serum positive for HBAg in cases of chronic glomerulonephritis, especially membranous glomerulonephritis, is frequently associated with a clinically latent chronic hepatitis.

5957 VIRAL HEPATITIS AND BONE MARROW APLASIA. (Fre.) Claude, R.; Michel, J. P.; Laubie, B.; Hirtz, J.; Pillegand, B. (Hopital General, 87 Limoges, France). *Med. Chir. Dig.* 4(3):149-154; 1975.

A case report is presented of a 37-yr-old man who developed posthepatic medullary aplasia 40 days after the onset of a cytolytic jaundice. The hemogram and myelogram revealed a triple hematopoietic deficiency (2% RBC, 11% granulocytes, and 87% mononucleated cells). Despite polyvitamin and corticosteroid (30 mg delta cortisone, 60 mg oxymethalone, p.o.) treatment, hemorrhaging symptoms worsened (epistaxis, melena, and hematuria), leading to death 8 months after the onset of the hepatitis. Present pathogenic hypotheses from the literature suggest a viral or autoimmune link between medullary aplasia and viral hepatitis.

5958 PRESENT STATE OF THE EPIDEMIOLOGIC RESEARCH ON THE AUSTRALIA ANTIGEN IN SENEGAL. (Fre.) Diebolt, G.; Baylet, R.; Linhard, J. (Faculte de Medecine de Dakar, 34000 Montpellier, France). *Pathol. Biol. (Paris)* 23(6):429-432; 1975.

LIVER AND BILIARY TRACT

Chronic Hepatitis

5974 IMMUNE COMPLEXES IN CHRONIC HEPATITIS. (Eng.) Fodor, O.; Parau, N.; Fodor, I.; Radu, D.; Abrudan, O. (IIIth Medical Clinique, Cluj, Rumania). *Acta Hepatogastroenterol.* 23(3): 172-176; 1976.

The incidence and possible role of immune complexes in chronic hepatitis were studied in chronic hepatitis patients and in controls. Rheumatoid factors were present in 33.2% of 274 patients with hepatitis, and in 2.8% of 380 controls. Cryoglobulins occurred in 47.6% of 144 patients tested and in 4.7% of 42 controls. Anticomplementary activity was present in 34.2% of 52 patients and in 2% of 50 controls. No statistically significant loss of total complement was observed, but its C1 and C3 components exhibited lowered titers in 48.6% and 45.7%, resp., of 160 patients with chronic active hepatitis. The presence of rheumatoid factors in chronic hepatitis may be due to prolonged, viral, or other antigen stimulation, which results in the formation of antigammaglobulins capable of reacting with immunoglobulin G (IgG) from complexes. It is also possible that antigen-antibody reactions may result in structural alteration of the antibody part of the complex, and stimulate the formation of a previously described serum factor called anti-antibody. These complexes may localize in any area of inflammation and induce subsequent damage; it is likely that hepatic lesions can be linked to a chain of events involving formation of an immunoglobulin complex with antiglobulin factors and complement fixation. Since immunoglobulins from complexes isolated as mixed IgG-IgM cryoglobulins behave both as anti-hepatitis B-antibody and as an anti-IgG rheumatoid factor, the IgM immunoglobulins must be produced in response to hepatitis B antigen and also to the hepatitis B antigen-hepatitis B antibody-complex.

5975 SERUM INHIBITORY FACTORS (SIF) IN PATIENTS WITH ACUTE AND CHRONIC HEPATITIS AND THEIR CLINICAL SIGNIFICANCE. (Eng.) Brattig, N.; Berg, P. A. (Dept. Medicine, Univ. Tubingen, D-7400 Tubingen, Auf dem Schnarrenberg, W. Germany). *Clin. Exp. Immunol.* 25(1):40-49; 1976.

Sera from 18 patients with hepatitis B surface antigen (HBsAg)-positive viral hepatitis, 9 patients with chronic persisting hepatitis (CPH), and 6 juvenile patients with developing chronic active hepatitis (CAH) were tested for serum inhibitory factors (SIF) to correlate inhibitory activity with clinical, biochemical, and histologic parameters. These factors were also studied in 15 patients with HBsAg-positive and -negative CAH. Lymphocytes from 6 controls, 9 patients with acute HBsAg-positive hepatitis, and 11 patients with CAH were stimulated with 2, 10, and 50 μg phytohemagglutinin (PHA). HBsAg and HBsAb were detected by radioimmunoassay, and antibodies against smooth muscle (SMA), nuclei (ANA), mitochondria (AMA), and vascular endothelium were detected by immunofluorescence. All sera markedly depressed the PHA-induced transformation of normal lymphocytes during the first week, showing a mean index of 0.25 ± 0.12 ($p<0.001$). The serum inhibitory effect disappeared gradually, and after 4 weeks, 67% of the patients' sera had lost these factors; 7 weeks after onset, none showed inhibition activity. In six patients, SIF was also demonstrated during the incubation period, up to 4 weeks before onset of jaundice, and in one case, before the appearance of HBsAg. In patients with CPH, SIF was at the lower limit of the normal range (mean 0.74 ± 0.10) in a 3-yr follow-up. Strong and lasting inhibitory activity was observed in six young patients (age 10-27 yr) with a progressive course of CAH, who were followed-up for 4 yr; CAH was clinically and histologically evident in all patients when reexamined 1-3 yr after the first symptoms. Clinical status and liver biopsies correlated well with the serum inhibitory activity in 12 patients. It is concluded that SIF is produced in response to viral infections and released from lymphocytes as long as viral antigenic stimulus persists.

5976 PENICILLAMINE IN THE TREATMENT OF CHRONIC ACTIVE LIVER DISEASE. (Eng.) Stern, R.; Williams, R. (King's Coll. Hosp. Medical Sch., Denmark Hill, London, S.E.5, England). *Med. Chir. Dig.* 4(3):141-144; 1975.

Clinical experience with penicillamine in the treatment of chronic active liver disease (CALD) is summarized, together with the observed side-effects and the pharmacological actions that may make it valuable in the treatment of this condition. The two actions of the most relevance to the effectiveness of penicillamine in CALD are its ability to dissociate immunoglobulin molecules and its inhibitory effect on collagen biosynthesis. The earliest report of the use of penicillamine described two patients with subacute hepatic necrosis, who were treated with 1.8 g/day; after 6 months, the liver function tests returned to normal in both patients, and in one, a repeat liver biopsy showed the absence of histological progression of the lesion. Similar results were obtained in the treatment of a patient with cholestatic hepatitis. Subsequently, at least six authors have reported favorable results with the drug in series of up to 34 patients. Unfortunately, none of these series was controlled, and the histological criteria were not standardized, making comparison between results difficult. The most potentially dangerous side effect was the nephrotic syndrome, which may develop after months or years of treatment. The most common histological type was minimal lesion nephropathy, and in several series glomerular immune complexes with immunoglobulin G (IgG), IgM, or C'3 have been demonstrated. In most cases, the lesion is slowly reversible after cessation of the drug. Other side effects included allergic-type rash, intracutaneous hemorrhage over pressure points, epidermolysis bullosa, elastosis perforans serpiginosa, loss of taste acuity, and nausea and vomiting. The use of penicillamine is limited by a high frequency of side effects, and will only find a major place in the management of CALD if it proves to be superior to prednisone or other currently used forms of immunosuppressive therapy in reducing both the inflammatory and the fibrotic component of the liver lesion.

5977 COMPARISON OF LAPAROSCOPIC AND SCINTIGRAPHIC FINDINGS IN CHRONIC HEPATITIS, IN LIVER CIRRHOSIS, AND IN HEPATIC TUMORS. (Ita.) Vido, I.; Hundeshagen, H. H.; Becker, H.; Schmidt, F. W. Alcoholic Liver Disease

5986 KARYOGRAMS OF NORMAL AND FATTY LIVERS IN MAN. (Ger.) Klinge, O.; Ross, W.; Struder, E. (Pathologisches Institut der Universitat, D-8700 Wurzburg, Josef-Schneider-Str. 2, W. Germany). *Virchows Arch.* [*Pathol. Anat.*] 366(3):203-222; 1975.

The karyograms of normal human livers (50 biopsies from patients of varied age) and of fatty livers (350 biopsies from patients with diabetes, alcoholism, and fatty cirrhosis) were investigated. The nuclear diameters were measured, and the cut surface of the nuclei was determined. The normal liver in each age group was characterized by a well-defined nuclear pattern that was specific for this organ. In the third decade, nuclei of the main class predominated. In later decades, two classes of large nuclei gradually appeared and reached their maximum after the 50th yr. In the seventh decade, a reduction of the cut nuclear surface took place in all the categories, presumably because of a reduction in function. The increase in the number of large nuclei was explained by abortive karyokineses, which in the course of the normal cell turnover, increasingly replace normal mitoses. This was attributed to disturbances of the achromatic apparatus, which occurs with increasing age. Alcoholic and diabetic, fatty change led to the formation of particularly large nuclei. This appeared to depend on the volume of the individual fat droplet within the individual cell rather than on the degree of change of the whole liver. Factors that may influence the formation of enlarged nuclei in the fatty liver include: the general tendency of the aging liver to form large nuclei, the toxic effect of alcohol on the hepatocytes in alcoholics with fatty liver, and the impairment of mitosis by the space-occupying effect of fat droplets. In addition to the impairment of mitoses, a pathologic swelling of the nucleus is assumed to contribute to the increased number of large nuclei seen in the karyogram. This swelling may be a result of the restructuring of the liver and/or of noxious stimuli. The increase in the number of small nuclei in the alcoholic or diabetic fatty liver, as well as in fatty cirrhosis, although marked, was not easily noted on scanning of the slide; only a numerical evaluation fully revealed its extent and significance. The increased number of small nuclei in the fatty livers was approximately equal. This increase may result from an adaptation of the cell to the increased functional load of the organ. In cirrhosis, an adaptation to an impaired metabolic state may also be involved.

5987 ELEVATED SERUM GAMMA-GLUTAMYL-TRANSFERASE (TRANSPEPTIDASE) AND HISTOLOGICAL LIVER DAMAGE IN ALCOHOLISM. (Eng.) Wu, A.; Slavin, G.; Levi, A. J. (Northwick Park Hosp. Clinical Res. Center, Burlington, Ontario, L7P 3B3 Canada). *Am. J. Gastroenterol.* 65(4):318-323; 1976.

The relation of serum gamma-glutamyl-transferase (transpeptidase, GGTP) activity to other biochemical liver function tests and to histological liver damage was investigated in 66 alcoholic patients (949 men, 17 women, aged 30-78 yr). Blood samples were taken from and percutaneous liver biopsy was performed on all patients. Elevated serum GGTP was the most common finding (74%), and the only finding in seven patients. There were significant correlations between serum GGTP and serum aspartate aminotransferase (AsT, $p<0.01$) and alkaline phosphatase (AP, $p<0.01$). No significant correlation was seen between the average daily alcohol consumption and serum GGTP ($p>0.05$). On liver biopsy, 6 patients had normal livers, 22 showed fatty change, 12 showed severe hepatofibrosis, 8 showed alcoholic hepatitis, and 18 showed cirrhosis. Serum GGTP elevation was most common among the cirrhotics (17 of 18). The mean serum GGTP value was statistically different from normal ($p<0.005$) and fatty change ($p<0.05$) groups. Elevated serum GGTP levels were present in 9 of 19 patients without histological evidence of cellular necrosis, but other histological abnormalities were present in 8 of the 9. The results show that while elevated serum GGTP levels in alcoholism may be partly related to structural liver damage, other mechanisms, such as hepatic microsomal enzyme induction or alcoholic pancreatic damage, may also play a role.

5988 HEPATITIS B VIRUS INFECTION IN THE WISKOTT-ALDRICH SYNDROME. (Eng.) Gerety, R. J.; Poplack, D. G.; Hoofnagle, J. H.; Blaese, R. M.; Holland, P. V.; Barker, L. F. (Div. Blood and Blood Products, Bureau Biologics, 8800 Rockville Pike, Bethesda, MD 20014). *J. Pediatr.* 88(4, part 1): 561-564; 1976.

Because of the immunologic deficits demonstrated by children with the Wiskott-Aldrich syndrome, and because of their frequent exposure to hepatitis B virus (HBV) in the course of transfusion therapy for thrombocytopenia, the sera of 12 patients with this syndrome were tested for evidence of HBV infection. All but one of the 12 children had received multiple transfusions. Evidence of HBV infection was found in three patients, all of whom had received multiple transfusions. The first patient had hepatitis B surface antigen (HBsAg, subtype *adw*), which persisted for at least 3 months; antibody to hepatitis B core antigen (anti-HBc) was subsequently detected and rose to a high titer (1:128) before declining and becoming undetectable at bleedings 2-4 yr later. Antibody to HBsAg (anti-HBs) was first detected at the 2-yr follow-up. The serum of the second patient was positive for anti-HBs and anti-HBc, the former remaining persistent. HBsAg was not detected. The serum of the third patient revealed only anti-HBs, which persisted at a low titer until his death 2 months later. In the first two patients, liver function tests revealed mildly elevated SGOT (85-321 Karmen U in the first patient; 64-93 u s/b in the second patient) and SGPT (87-232 and 82-85

Karmen U, resp.), but bilirubin levels were normal. It was obvious that these three children had not experienced severe viral hepatitis and had not developed the chronic HBsAg carrier state. The data suggest that the immunologic defect present in Wiskott-Aldrich patients does not predispose to severe clinical type B hepatitis or to the chronic carrier state.

LIVER AND BILIARY TRACT

Cirrhosis

5992 BILIARY CIRRHOSIS: NOSOGRAPHIC AND THERAPEUTIC CHARACTERISTICS. (Ita.) Grossi, F.; Messini, F. (Scuola de Specializzazione in Malattie del Fegato e del Ricambio, Universita di Roma, Rome, Italy). *Clin. Ter.* 75(3):291-303; 1975.

Biliary cirrhoses are divided into two groups: primary biliary cirrhosis, and cirrhosis caused by extrahepatic and intrahepatic primary sclerosing cholangitis, by sclerosing cholangitis, and by chronic cholestasis. The morphology, pathogenesis, and clinical symptoms of primary biliary cirrhosis are reviewed. Therapy emphasizes symptomatic treatment of pruritus and malabsorption of fats, liposoluble vitamins, and calcium; pathogenetic cures are being sought.

5993 ORNITHINE CARBAMOYLTRANSFERASE (O.C.T.) IN HEPATIC CIRRHOSIS, COMPARED TO OTHER ENZYMATIC TESTS. (Ita.) De Simone, E.; Casolaro, M.; Belli, M. G. (Ospedali Riuniti di Napoli, Naples, Italy). *Rass. Int. Clin. Ter.* 55(11): 663-668; 1975.

Ornithine carbamoyltransferase (OCT) serum levels were examined in 63 patients with hepatic cirrhosis at various stages. The levels of OCT are indicative of the activity of the disease even in cases of apparent clinical compensation and normal transaminases. Variations in the serum level of OCT are indicative of disorders of the mitochondria, which are independent of lysis phenomena of the membrane or of necrosis of the cell. This characteristic distinguishes OCT from the lysis enzymes, glutamic-pyruvic transaminase and glutamic-oxaloacetic transaminase, also measured in the serum of these patients. Alcoholic cirrhosis causes frequent and notable rises in OCT and the enzyme, gamma glutamyl transpeptidase (gamma GT). This is due to increased induction for gamma GT and to lesions of the mitochondria for OCT.

5994 THE VALUE OF THE USE OF AN ACIDIFIER IN DIURETIC TREATMENT IN THE COURSE OF THERAPY FOR CIRRHOSES. (Fre.) Bonvarlet, P. (Service de la Clinique des Maladies de l'Appareil Digestif, Hopital Regional, Centre Hospitalier Universitaire, 59000 Lille, France). *Entretiens Bichat Ther.* 1975: 133-136.

Twenty-seven patients with cirrhosis (17 with jaundice, edema, ascites, and oliguria; 10 with ascites and oliguria; and 3 with encephalopathy) were administered arginine hydrochloride either by perfusion (25 g/day) or p.o. (25-30 g/day) in addition to i.v. or p.o. furosemide. Doses of furosemide varied according to the diuresis required. While recovery of diuresis in patients treated i.v. was excellent, acidosis was rapid and difficult to control, and electrolyte balance disturbances, especially hypokalemia, were major. Complications in patients treated p.o. were not as marked nor was the recovery of diuresis. While ascites disappeared, jaundice persisted. Encephalopathy remained unchanged. The study confirmed the acidifying role of arginine as well as its beneficial effect on diuresis.

5995 EFFECTS OF ANTICOPPER THERAPY ON HEPATOCELLULAR MITOCHONDRIA IN PATIENTS WITH WILSON'S DISEASE: AN ULTRASTRUCTURAL AND STEREOLOGICAL STUDY.

(Eng.) Sternlieb, I.; Feldmann, G. (Albert Einstein Coll. Medicine, 1300 Morris Park Ave., Bronx, NY 10461). *Gastroenterology* 71(3): 457-461; 1976.

Ultrastructural findings in hepatocellular mitochondria of seven patients with Wilson's disease were compared by means of stereological techniques before and after anticopper treatment. Needle biopsies were taken before and after 3-5 yr of therapy with p.o. D-penicillamine and a low copper diet. Electron photomicrographs were made, and for stereological analysis, were projected onto a screen at a magnification of 24,000 x. Profound mitochondrial abnormalities, initially present in four of the patients, were reduced in severity and frequency in three; slight improvement occurred in two others. Hepatic copper concentrations decreased markedly in three patients, correlating with morphological improvement. Stereological analysis showed that the mean volume density of mitochondria was 18.2% before and 19.3% after treatment. Values in a normal control group were 17.03%. The mean surface density of external mitochondrial membranes was 1.15 μ^2/μ^3 before and 1.32 μ^2/μ^3 after treatment (control, 1.03 μ^2/μ^3). The mean surface-to-volume ratio was 6.22 μ^2/μ^3 and 6.67 μ^2/μ^3 after treatment (control, 6.13 μ^2/μ^3). The ranges of counts of mitochondrial profiles per unit surface overlapped: 0.25-0.47 and 0.03-0.48 mitochondria/μ^2 in pre- and post-treatment specimens, resp. The results show that improvement of certain cytological abnormalities is detectable at an ultrastructural level and also imply that the mitochondrial changes are the result of copper toxicity.

5996 COMPARISON OF VITAMIN D AND 25-HYDROXY-VITAMIN-D IN THE THERAPY OF PRIMARY BILIARY CIRRHOSIS.

(Eng.) Wagonfeld, J. B.; Bolt, M.; Boyer, J. L.; Nemchausky, B. A.; Vander Horst, J.; Rosenberg, I. H. (Section Gastroenterology, Univ. Chicago, Chicago, IL 60637). *Lancet* 2(7982):391-393; 1976.

The serum 25-hydroxy-vitamin D and bone mineral content were determined in eight women (aged 35-62 yr) with primary biliary cirrhosis, and the effect of p.o. and parenteral vitamin D therapy was compared with that of p.o. 25-hydroxy-vitamin D therapy. Skeletal mineralization was assessed in each patient by metacarpal cortical thickness and by proton-beam absorption. Serum 25-hydroxy-vitamin D levels were determined by a competitive protein-binding method. The patients had a mean cortical thickness (3.60 mm) and an absorption coefficient (1.82 cm^{-1}), which was significantly less than those of 17 age- and sex-matched controls (5.11 mm and 2.08 cm^{-1}, resp.). In six untreated patients with primary biliary cirrhosis, the mean serum 25-hydroxy-vitamin D level was 4.4 ng/ml, significantly less than in the controls (23.8 ng/ml). During 3 months of therapy with s.c. vitamin D (100,000-500,000 U/month), the patients' mean absorption coefficient decreased 10%. After p.o. 25-hydroxy-vitamin D (100-200 μg/day) therapy for 3 months, the coefficient increased by 5%. None of the six patients in whom both pre- and post-treatment samples were available, responded to 3-6 months of either p.o. or s.c. vitamin D with an elevation in the serum level of 25-hydroxy-vitamin D. At the end of 3-6 months, a decrease in bone mineral content greater than 2% occurred in all but two patients. Only one patient with a normal serum 25-hydroxy-vitamin D level after s.c. vitamin D therapy showed improvement in bone mineral content. In contrast, all patients responded to 25-hydroxy-vitamin D, with a rise in serum 25-hydroxy-vitamin D levels to normal or high values. The linear absorption coefficient either increased or remained stable in all but one patient. 25-Hydroxy-vitamin D therapy may be the preferred form of vitamin D therapy in primary biliary cirrhosis.

5997 PORTACAVAL ANASTOMOSIS FOR ASCITES: 16 CASES.

(Fre.) Levy, V. G.; Theodore, C.; Hivet, M.; Hautefeuille, P.; Huguet, C.; Caroli, J. (Hopital St.-Antoine, 184, rue Fg Saint-Antoine, 75012 Paris, France). *Med. Chir. Dig.* 4(2):93-98; 1975.

Sixteen patients with ascites (12 cirrhoses and 4 Budd-Chiari syndromes) underwent portacaval anastomosis (9 termino-terminal, 4 latero-lateral, and 3 mesenterio-caval with a dacron prosthesis). There were four deaths within 2 months (1 electrolyte imbalance, 2 infections, and 1 untimely surgery), three within 3-4 months (1 hepatic deterioration and 2 ascites with thrombosed or inadequate anastomoses); two patients died 30 and 88 months later, resp., of nonhepatic causes (1 amylosis and 1 hemorrhaging bulbous ulcer). The remaining seven patients were cured, although a few moderate transitory ascites did occur. Better pre- and postoperative care should be provided to avoid loss of fluid during surgery and electrolyte disorders.

5998 CHECKING THE PERMEABILITY OF SURGICAL PORTA CAVAL ANASTOMOSES BY ARTERIOGRAPHY.

(Fre.) L'Hermine, C.; Vankemmel, M.; Quandalle, P.; Dehaene, J. L.; Maillard, J. P. (C.H.U., F 59000 Lille, France). *J. Radiol. Electrol. Med. Nucl.* 57(3):219-225; 1976.

Arterioportography is recommended as a technique preferable to phlebography for checking the success of portacaval anastomoses. The procedure, simple and safe, was performed in 18 anastomoses (11 splenorenal, 3 terminoterminal portacaval, 2 laterolateral portacaval, and 2 mesenteriocaval). It was always possible to determine whether the anastomosis was permeable, by visibility of the anastomosis and/or opacification of the lower vena cava. The nonvisibility of the anastomosis and of the lower vena cava and the opacification of varicosis are signs of a nonfunctional anastomosis. The quality of the opacification is somewhat inferior to that of selective phlebography by the caval route. Arteriography provides important hemodynamic data on the functioning of the anastomosis and on portal circulation.

999 IMMUNOLOGICAL STUDIES IN FAMILIAL PRIMARY BILIARY CIRRHOSIS. (Eng.) Tong, M. J.; ies, K. M.; Reynolds, T. B.; Quismorio, F. P. (John esley Hosp., 2826 South Hope St., Los Angeles, CA 0007). *Gastroenterology* 71(2):305-307; 1976.

ests for cell-mediated immunity and the presence f autoantibodies were performed in a 63-yr-old other and her 38-yr-old daughter, who both had rimary biliary cirrhosis. Their case histories re presented. Lymphocyte transformation to hytohemagglutinin, delayed cutaneous response to ne or more skin test antigens, and the percentage f peripheral thymus-derived (T) and bone marrow-erived (B) lymphocytes were normal in both patients. lthough successful in the mother, dinitrochloro-enzene sensitization was not achieved in the aughter. Histocompatibility antigens 1 and 8, ele-ated levels of immunoglobulin M (0.34 in the daughte .42 in the mother), and antibodies to mitochondria, mooth muscle, and skeletal muscle were present in oth patients. The clinical course was more severe n the daughter, who developed portal hypertension ith bleeding esophageal varices requiring porta-aval anastomosis. Except for intermittent ruritus, the mother has remained asymptomatic.

000 ACTIVE AND PASSIVE FIBROUS SEPTA IN MAJOR HEPATIC FIBROSIS IN MAN: DETECTION OF OLLAGEN HYPERFIBERS WITH ELECTRON MICROSCOPY. (Fre.) eyrol, S.; Grimaud, J.-A.; Borojevic, R. (Institut asteur de Lyon, 77, rue Pasteur, 69007 Lyon, France). *.R. Acad. Sci.* [*D*] *(Paris)* 282(3):333-336; 1976.

he ultrastructural study of severe hepatic fibrosis evealed collagen hyperfibers, characterized by their arge diameter, in the septa. These hyperfibers may erve as a qualitative evaluation of the fibrosis, n terms of stability and potential reversibility. he conditions accompanying their elaboration, in-ense inflammation and fibrogenesis, are always igns of poor prognosis. There are two possible nterpretations of the morphogenesis of collagen in he conjunctive tissue: (1) The collagen hyper-ibers may represent *in vivo* disorganization of the ollagen fibers, secondary to enzyme liberation odifying the microenvironment of the fibers. Thus, he hyperfibers may be a result of fiber alteration, reliminary to the accelerated fibrolysis of inter-titial or cellular origin, indicating the rapid re-ersibility of the fibrosis. (2) The fibers may be result of hyperpolymerization of collagen fibrils. he hyperfibers would then represent a form of col-agen more stable than the normal fiber, and the ossibility of a rapid reversal of the fibrosis ould be eliminated.

001 CHANGES OF EEG AND PULMONARY VENOUS ADMIXTURE DURING A PROTEIN LOAD IN PATIENTS ITH CIRRHOSIS. (Eng.) Schomerus, H.; Buchta, I.; rndt, H. (Medizinische Universitatsklinik, Otfried-uller-Strasse, D-7400 Tubingen, W. Germany). *Eur. . Clin. Invest.* 5(6):515-520; 1975.

tudies were carried out to determine whether minor EEG slowing induced by a protein load in 21 patients with cirrhosis was associated with a measurable increase in venous admixture. These patients and 24 age-matched controls were studied before and after a protein load (120 g protein/day for 1 week). An EEG was recorded, and a visual assessment of frequency pattern was performed. Venous admixture was estimated during hyperoxia. According to the EEG frequency pattern, the patient group with cirrhosis was subdivided into seven patients with EEG slowing after the protein load and 14 without. The resting arterial blood gases were not significantly different in the two groups. After the protein load, all cirrhotic patients had a mean alveolar arterial oxygen difference ($AaDO_2$), that was significantly higher than controls ($p<0.025$). The increase in $AaDO_2$ was significantly larger in cirrhotics showing EEG slowing than in those without EEG slowing ($p<0.01$) or controls ($p<0.01$). The fractional venous admixture was increased significantly in cirrhotics with EEG slowing, compared with that in cirrhotics without slowing and with controls. The results confirm earlier findings that intrapulmonary venous admixture is not a constant phenomenon, but a rapidly changing functional parameter in patients with chronic liver disease.

6002 LITHOGENOUS BILE AND LIVER CIRRHOSIS. (Fre.) Solis-Herruzo, J. A. (Hospital Clinico de la Facultad de Medicina de Madrid, Universidad Complutense, Madrid, Spain). *Med Chir.* 4(4):211-217; 1975.

The composition of the gallbladder bile of 29 cirrhotic patients (15 septal cirrhoses and 14 postnecrotic cirrhoses) and of 11 normal subjects was studied. Samples were obtained by puncture during laparoscopy. Results show that in the cirrhotic patients the incidence of gallbladder lithiasis was high (24%). The bile frequently contained cholesterol microcrystals (69%), a condition that favors the formation of cholesterol calculi. Cholesterol excretion was normal while that of phospholipids was very high ($p<0.001$) and that of biliary acids very low ($p<0.001$). Lipids exceeded the micellar zone of Small's triangle in 69% of the patients. The micellar instability of the bile in cirrhotic patients combined with an excess of bilirubin may be responsible for the higher incidence of gallbladder lithiasis in these patients. Other factors, such as stasis of bile, may also contribute to the formation of calculi.

6003 MASSIVE SPLENIC INFARCTION IN CIRRHOSIS: REPORT OF A CASE WITH SPONTANEOUS DISAPPEARANCE OF HYPERSPLENISM. (Eng.) Capron, J.-P.; Chivrac, D.; Dupas, J.-L.; Remond, A.; Ossart, J.-L.; Lorriaux, A. (Clinique Medicale A, Centre Hospitalier Universitaire, 1 Place Victor Pauchet, 80030 Amiens Cedex, France). *Gastroenterology* 71(2):308-310; 1976.

The case of a 45-yr-old male cirrhotic patient with massive splenic infarction is described. The patient presented with melena. Celiac angiography showed a normally opacified splenic artery and vein and a markedly enlarged spleen with large avascular zones. Splenic infarction was associated with the spontaneous disappearance of a syndrome of hypersplenism. Splenectomy was performed. Histological examination showed large foci of hemorrhagic necrosis, with multiple thromboses of the small arterial and venous vessels. The cause of this infarct remains unclear. This case may serve as a warning against the injudicious use of splenic artery embolism, because massive splenic infarction, with its dangers of splenic rupture, peritoneal hemorrhage, and splenic suppuration, may require splenectomy.

6004 INTRAHEPATIC ARTERIOPORTAL FISTULA SECONDARY TO A PORTAL THROMBOSIS IN CIRRHOSIS. (Fre.) Paris, J. C.; L'Hermine, C.; Tonnel, A. B.; Dehaene, J. L.; Plouvier, B.; Pagniez, B.; Pommelet, P. (Clinique des Maladies de l'Appareil digestif, C.H.U., F 59000 Lille, France). *J. Radiol. Electrol. Med. Nucl.* 57(3):227-232; 1976.

The case of a 62-yr-old woman with cirrhosis accompanied by an abundant recurring pleural effusion is reported. Celiac arteriography revealed a massive intrahepatic arterioportal fistula in the region of a segment of the left hepatic lobe. Subsequent arteriography detected stagnation of the contrast medium in the left branch of the portal vein which was opacified from the fistula up to the hilar region. It was impossible to study the portal system angiographically due to a complete atheromatous thrombosis of the superior mesenteric artery. The portal thrombosis was only suspected due to the stagnation of the contrast medium and to the absence of any other cause for a traumatic or tumoral fistula. The patient died a few days later from hepatic insufficiency. A complete thrombosis of the portal trunk and a micronodular atrophic cirrhosis were revealed at autopsy. There were no other intrahepatic lesions capable of explaining the arterioportal fistula.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

6017 VISCOSITY AND OSMOLALITY OF ABNORMAL BILES. (Eng.) Cowie, A. G. A.; Sutor, D. J. (Univ. Coll. Hosp. Medical Sch., Univ. St., London WC 1, England). *Digestion* 13(5):312-315; 1975.

The osmolality and viscosity of gallbladder and common duct bile were measured and related to the gallbladder function and gallstone composition of 28 patients undergoing surgery for gallstone disease. The osmolality of the bile was estimated by measuring the depression of the freezing point, and the relative viscosity was measured at room temperature using a capillary viscometer. The mean relative viscosity of bile in patients with nonfunctioning gallbladders (15.09 ± 4.17, 17 measurements) was greater than in patients with functioning gallbladders (7.30 ± 2.89, 7 measurements, $p<0.02$), and the mean osmolality in patients with nonfunctioning gallbladders (296 ± 6 mOsm/1, 16 measurements) was less than in those with functioning gallbladders (324 ± 10 mOsm/1, 7 measurements, $p<0.001$). Although this trend was seen when the patients were divided into groups according to the type of gallstone (cholesterol, cholesterol + calcium, or calcium salts), the differences were not significant. There were no significant differences in the mean viscosity and osmolality of biles associated with the different types of stones. The mean viscosity of bile from both functioning and nonfunctioning gallbladders for all patients was greater than that of bile from the common duct (1.41 ± 0.07). These and previously reported studies suggest that the mucus content of the gallbladder can vary considerably and that it is usually greater in nonfunctioning gallbladders.

6018 EFFECT OF CALCIUM ION ON THE STATE OF SOLUTION AND CHOLESTEROL SOLUBILIZATION IN BILE. (Jpn.) Itoh, H. (Faculty Medicine, Kyushu Univ., Fukuoka, Japan). *Fukuoka Acta Med.* 66(5):351-367; 1975.

The effect of the calcium ion on the solution state of bile and its cholesterol solubilization was studied using a model bile (aqueous bile salt-lecithin solution) and human bile. The model bile was composed of 46.5 mM of sodium cholate, sodium chenodeoxycholate, or sodium deoxycholate aqueous solutions, with or without 8.6 mM lecithin. By adding calcium chloride to the model bile solutions, the formation of gel and precipitation was examined in relation to the calcium ion concentration. Gel formation occurred in the sodium cholate system with the addition of calcium chloride. The minimum calcium concentration for gelation in the sodium cholate without lecithin system was 16 mM; it was 45 mM when with lecithin. No gel formation could be observed in the sodium deoxycholate-calcium system, but precipitation occurred with the addition of the calcium ion. The minimum calcium concentration for precipitation formation was 1.5 mM in the system with lecithin and 5 mM in the system without it. The time required for gel formation increased as the calcium ion concentration decreased. Gel formation occurred in less than 30 min when 30 mM calcium was used in sodium cholate, and it was about 300 min when 20 mM calcium was used. By using an isolated human bile, the effect of calcium on cholesterol solubilization was examined. Human bile (5 ml) and cholesterol powder (3 ml) were placed in an ampule together with various concentrations of calcium chloride solution. The ampule was shaken for 48 hr at 20 C, and the solution was analyzed for the concentrations of solubilized cholesterol, cholate, deoxycholate, chenodeoxycholate, lecithin, and calcium. The concentration of solubilized cholesterol did not show a clear change up to the addition of 5 mM calcium. When the addition of calcium was greater than 10 mM, the concentration of solubilized cholesterol decreased as the calcium increased; the cholesterol concentration was 1.94 and 1.06 mM when the calcium concentration used was 10 mM and 100 mM, resp. The cholate concentration changed from 14.1 to 12.7 mM when the calcium concentration was changed from 2 to 100 mM.

6019 ACTION OF METHYL-4-UMBELLIFERONE ON THE HYDRODYNAMICS OF THE COMMON BILE DUCT IN MAN: PEROPERATIVE RADIOMANODEBITMETRIC STUDY. (Fre.) Vayre, P.; Hureau, J. (Clinique Therapeutique Chirurgicale, Hopital Vaugirard, rue de Vaugirard, 75015 Paris, France). *Med. Chir. Dig.* 3(4):293-297; 1974.

The immediate effect of an i.v. injection of 0.6 g of methyl-4-umbelliferone on common bile duct (CBD) hydrodynamics was studied in 105 patients undergoing biliary surgery. There was a 10-50% fall in pressure in all but 34/38 normal CBD, 6/12 hypotonic CBD, 12/12 mixed hypertonias, and 35/35 functional hypertonias; there was no effect in 8/8 organic hypertonias. Methyl-4-umbelliferone can be used when the cardiovascular condition of a patient proscribes amyl nitrite. In functional hypertonias, it can be used peroperatively as a pharmacodynamic test as it normalizes manometric results. Use of the drug in medical treatment of biliary dyskinesis should be explored since the present study confirms the myorelaxant and spasmolytic effect of methyl-4-umbelliferone on the common bile duct and the sphincter of Oddi.

6020 FLOW RATES AND MANOMETRY IN BILIARY SURGERY.

(Eng.) White, T. T. (Univ. Illinois, Medical Center, Chicago, IL). *Chir. Gastroenterol.* 9(4):469-473; 1975.

The value of biliary manometry and the determination of flow rates in the detection of common bile duct pathology were assessed in 300 patients undergoing biliary surgery. The value of cholangiography was also determined. A simplified flow and pressure apparatus, which consists of a 50-ml syringe, a length of plastic tubing, and a plastic needle, was used. The average resting pressure in a normal common bile duct was 11.8 cm, and in obstructed ducts, 18.4 cm. The flow in the normal duct was 23.0 and in the obstructed ducts 5.8. Of the 200 patients who were followed up for 3-5 yr, 131 had normal flow and pressure and normal ducts with no stones at surgery. Abnormal flow and pressure and abnormal ducts were seen in 30 patients. The results were equivocal in 19 patients, and technical failures occurred in the remaining 20 patients. The accuracy of cholangiography alone in the detection of bile duct pathology was 89%. The overall accuracy of pressure determination alone was 93%, for flow determination 93%, and for combined flow and pressure determination 94.5%. Among the patients followed up for 3-5 yr, there were 22 patients complaining of pain after eating, thought to be due to colitis or duodenal ulcer. The authors conclude that biliary manometry and flow rate determinations are useful methods for screening as a supplement to cholangiography in apparently normal people.

6021 BILE DUCT CARCINOMA MIMICKING CHRONIC LIVER DISEASE.

(Eng.) Pelleya-Kouri, R.; Dusol, M., Jr.; Orta, D.; Pereiras, R.; Clark, R.; Schiff, E. R. (Univ. Miami Sch. Medicine, Miami, FL). *Arch. Intern. Med.* 136(9):1051-1054; 1976.

The case of an 84-yr-old man with cholangiocarcinoma at the confluence of the major hepatic ducts is reported. The patient had experienced three separate episodes of jaundice, each of which had cleared spontaneously without specific therapy. During one episode, the total serum bilirubin, serum alkaline phosphatase, and SGOT levels rose to as high as 10.4 mg/100 ml (direct, 7.6 mg/100 ml), 880 mIU/ml, and 425 mIU/ml, resp., before returning to normal. There was one unusually long anicteric interval of at least 14 months. A liver biopsy performed during the first episode of jaundice showed pronounced pericholangitis and centrilobular cholestasis, which were considered to be consistent with extrahepatic obstruction. The results of a liver scan were normal. During another episode of jaundice, a percutaneous transhepatic cholangiogram disclosed partial obstruction of the left hepatic duct, close to the bifurcation at the porta hepatis. Although a bile duct carcinoma was suspected, surgery was not performed. At the patient's final hospitalization, emergency endoscopy showed bleeding esophageal varices. The results of a liver scan were consistent with hepatic cirrhosis and portal hypertension. Hepatic encephalopathy rapidly ensued, and total serum bilirubin, serum alkaline phosphatase, and SGOT levels rose to 26 mg/100 ml, 1,020 mIU/ml, and 300 mIU/ml, resp. At autopsy, an adenocarcinoma was found at the confluence of the major hepatic ducts. Histological examination revealed invasion of cholangiocarcinoma into the ducts and vascular channels with desmoplastic changes. A 1.3-cm cyst was found distal to the cystic duct and just after the formation of the common bile duct, which negates the possibility that the cyst contributed to the intermittent mechanical obstruction at the bifurcation. Other possible mechanisms might have been edema and inflammation of the ductules and/or spasm of the smooth muscle in the large ducts. The hyperbilirubinemia in this patient appears to involve more than just simple mechanical obstruction of the biliary tree.

6022 MARKED INCREASE IN SERUM LEVELS OF LIVER ENZYMES IN PATIENTS RECEIVING CHENIC ACID AND PHENOBARBITAL FOR GALLSTONE DISSOLUTION.

(Eng.) Menghini, G.; Pallotta, B. (General Provincial Hosp., Macerata, Italy). *Digestion* 14(2):163-169; 1976.

Three of 16 patients receiving chenic acid (20 mg/kg/day) and phenobarbital (60 mg/day) for gallstone dissolution developed marked increases in serum SGOT-SGPT and alkaline phosphatase levels without associated symptoms. In the three patients, the elevated serum SGOT levels ranged between 210 and 1,350 mIU/ml; SGPT ranged between 600 and 1,400 mIU/ml; and alkaline phosphatase ranged between 77 and 309 King-Armstrong U. Liver biopsy in one patient showed cellular infiltration with neutrophils and eosinophils, suggestive of a hypersensitivity reaction. Enzyme levels returned to normal following cessation of chenotherapy, and a second biopsy 3 months later was normal. In this patient, a challenge with chenic acid (250 mg/day) was again followed by a marked elevation in SGOT-SGPT and alkaline phosphatase. These patients are the first to show marked elevation in liver enzyme levels during chenotherapy, and the mechanism and significance are unclear.

6023 PREVALENCE OF CHOLELITHIASIS IN MEN AND WOMEN INGESTING A SERUM-CHOLESTEROL-LOWERING DIET.

(Eng.) Miettinen, M.; Turpeinen,

O.; Karvonen, M. J.; Paavilainen, E.; Ekosuo, R. (Coll. Veterinary Medicine, Hameentie 57, SF-00550, Helsinki 55, Finland). *Ann. Clin. Res.* 8(2):111-116; 1976.

The prevalence of gallstones was studied in autopsied male and female patients of two mental hospitals to determine whether a serum cholesterol-lowering diet is conducive to cholelithiasis. In the experimental diet, ordinary milk was replaced by an emulsion of soybean oil in skim milk, and butter and ordinary margarine were replaced by a soft margarine with a high polyunsaturated fatty acid content. The fatty acid compositions were very different in the two diets, The prevalence of gallstones was 22.5% in men on the cholesterol-lowering diet (20 of 89) and 25% of those on a normal diet (11 of 44); in women 42% on the cholesterol-lowering diet had gallstones (151 of 262), while 47% of those on a normal diet did (29 of 62). Men on the normal diet were somewhat younger (difference of 2.7 yr in the median age), while women were more nearly of the same age (difference of 0.8 yr in the median age). No significant correlation was found between gallstones and obesity. It is concluded that the cholesterol-lowering diet was not lithogenic.

6024 ENDOSCOPIC CHOLANGIOGRAPHY IN THE DIAGNOSIS OF OBSTRUCTIVE JAUNDICE. (Jpn.) Ohishi, H.; Sunagawa, M.; Hachiya, T.; Aburatani, R.; Miyata, Y.; Miura, T.; Utimoto, I.; Toyoda, T.; Fukai, Y. (Nara Medical Univ., Nara, Japan). *J. Nara Med. Assoc.* 25(4/5):343-349; 1974.

The diagnosis of four cases of obstructive jaundice by endoscopic cholangiography is reviewed. In the first case, a 65-yr-old man was diagnosed as having obstructive jaundice due to stones in the common bile duct. In the second case, a 61-yr-old man had developed obstructive jaundice due to a malignant tumor in the biliary tract, complicated by stones in the biliary tract. In the third case, a 66-yr-old man also developed obstructive jaundice due to a tumor; his case was complicated by the presence of stones in the biliary tract. The final case of obstructive jaundice occurred in a 68-yr-old woman with carcinoma in the papilla of Vater. Endoscopic cholangiography was found to be an effective technique for the diagnosis of obstructive jaundice when used in conjunction with angiography, percutaneous transhepatic cholangiography, and hypotonic duodenography. Endoscopic cholangiography is a relatively safe and simple diagnostic technique for obstructive jaundice, since a relatively clear graph can be obtained in a single, atraumatic examination.

6025 GLOBAL DILATATION OF THE BILE DUCTS AND LITHIASIS IN CHILDREN. (Fre.) Meck, J. M.; Rossier, A. (Hopital Saint-Vincent-de-Paul, 74, avenue Denfert-Rochereau, 75014 Paris, France). *Med. Chir. Dig.* 4(4):247-250; 1975.

The literature is reviewed and the case history of an 11.5-yr-old boy with primary intrahepatic lithiasis and extrahepatic lithiasis of the bile ducts is presented. Of interest was a complete absence of jaundice and no obstruction of the intra- and extrahepatic bile ducts, despite global dilation and calculi. The patient, as usually recommended, underwent a Y-shaped termino-terminal anastomosis of the common bile duct and jejunum. This technique allows for good drainage and avoids retention, which may be caused by a diverticulum forming at the site of the anastomosis. Peroperative cholangiography is important as it explores the permeability of the common bile duct as well as the branches of the intrahepatic bile ducts.

6026 ASCENDING CHOLEDOCHAL PAPILLOMATOSIS. (Ger.) Schmidt, H.-D.; Brunner, H. (Chirurgische Klinik der Universitat, D-6500 Mainz, Langenbeckstr. 1, W. Germany). *Munch. Med. Wochenschr.* 118(6):163-166; 1976.

The case of a 44-yr-old man with ascending choledochal papillomatosis is reported. The patient was hospitalized for congestive jaundice following cholecystectomy with choledocus reconstruction, and duodenotomy with papillar expansion and subsequent T-drainage. At reoperation, the gallbladder yielded about 50 ml of a gelatinous mucous material; a choledochoduodenostomy was established. Two yr later, epigastric pain recurred. Gastroduodenoscopy revealed an apparent bile thrombus and other unidentifiable structures. At laparotomy, the head of the pancreas was found to have undergone cystic degeneration, and a large, flat tumor was present in the common bile duct. A duodenopancreatectomy was performed. Upon histological examination, all of the ducts, large and small, were seen to be filled with papillomas. Recovery proceeded smoothly; the elevated alkaline phosphatase levels normalized rapidly. Slight ascending cholangitis was apparent on follow-up 1 yr later. Ascending papillomatosis of the common bile duct should be regarded clinically as a malignant condition, since intrahepatic growth is inevitable. Radical surgery is the therapy of choice, but is not always possible. Removal of the diseased bile duct and duodenopancreatectomy may be performed as two separate procedures, if the patient's condition demands this and if malignant degeneration of the tumor has not occurred.

GENERAL

6041 THE GENESIS OF BOWEL SOUNDS: INFLUENCE OF VISCUS AND GASTROINTESTINAL CONTENT. (Eng.) Politzer, J.-P.; Devroede, G.; Vasseur, C.; Gerard, J.; Thibault, R. (Unite de Recherches Gastrointestinales et Department du Genie Electrique, Universite de Sherbrooke, Sherbrooke, Quebec, Canada). *Gastroenterology* 1(2):282-285; 1976.

A computer analysis of the influence of the stomach and small and large bowel on the genesis of bowel sounds was carried out. Eleven healthy volunteers were intubated p.o. with a multiple-lumen tube. Bowel sounds were recorded for 10 min when the tube was in the stomach, the upper jejunum, and the cecum, and while it was left intact *in situ*, or perfused with isotonic saline (15 ml/min), or with an equal mixture of isotonic saline and air (7.5 ml/min each). The effect of perfusion varied according to site; 46% of the sounds occurred while the tube was in the stomach, 32% in the jejunum, and 22% in the colon ($p<0.05$). There were two types of sounds. One type exceeded a preset threshold (S1) in amplitude, and was picked up by the computer. Its average absolute value for 20 msec remained inferior to nother preset threshold (S2). The number of sounds as stored in memory (NS--number of sounds having n amplitude exceeding S1/10 min). A second type f sound also exceeded S1, while its average absolute alue for 20 msec exceeded S2; this number of sounds NE--sounds having an amplitude exceeding S1, but aving also a 20-msec average amplitude above S2/10 in) was also stored. The latter group was composed f two types of sounds: some had a limited spectrum f low frequency (100 Hz) and were of high amplitude nd short (≈ 5 msec) duration (NE1); others had a igher and more dispersed frequency centered around 00 Hz (NE2). Fifty percent of high energy (NE) ounds appeared while the tube was in the stomach, 0% in the colon, and 20% in the jejunum ($p<0.005$). E1 were counted more often when the tube was in the olon (43%) than in the stomach (38%) or the jejunum 19%, $p<0.025$). In contrast, NE2 were present more ften when the tube was in the stomach (59%) than in he jejunum (24%) or the colon (17%, $p<0.005$). In he stomach and the colon, only the perfusion of the ir/saline mixture increased the number of sounds $p<0.025$), whereas the perfusion of saline increased he number of sounds ($p<0.025$) in the jejunum. The ir/saline mixture also increased the types of sounds eard in the stomach ($p<0.025$). It is concluded that he stomach is the most active site of production of owel sounds, followed by the colon and the small owel. The sounds differ in different sites, and the ype and number of sounds are influenced by viscus ontent.

6042 SERUM ANTIBODIES AND COPROANTIBODIES IN BACTERIAL INFECTIONS OF THE DIGESTIVE TRACT IN CHILDREN.

(Fre.) Laplane, R.; Begue, P.; Omanga, U. (Hopital Trousseau, 24, avenue du Docteur-Arnold-Netter, 75571 Paris Cedex 12, France). *Bull. Acad. Natl. Med. (Paris)* 159(7):596-600; 1975.

In order to study the immunological reaction to intestinal bacterial infections in children, fecal cultures were taken from 199 children (average age, 11.9 months), isolating 117 salmonellas, 90 enteropathogenic colibacilli, and 5 shigellas. Antigen extracted from the individual child's bacteria was used to measure serum antibody levels. Seroconversion occurred in 125/199 children, with a 65% rate of positive results for salmonella and 51% for *E. coli*; 99/125 of the positive children had digestive disorders. The rise in serum antibodies in half the healthy children suggests an asymptomatic subclinical illness. A comparative study of 65 children from Dakar (all with enterobacterial gastroenteritis) showed seroconversion in 79% of the latter, with 78% for salmonella and 86% for shigella. The percentage was highest in malnourished children, suggesting a hyperstimulation of the immunological system by bacterial and parasitic infections over a long period of time. Of 57 children (sampled from both groups) studied for fecal antibodies, 33 were found to be positive. In all 33 cases, the serum antibodies were positive, but in 9 seroconversion was delayed. There was no seroconversion in 21 of the remaining 24 without fecal antibodies. High rates of serum antibodies were constantly associated with an absence of fecal antibodies. It seems that the fecal antibodies appear early, before the serum antibodies, persist for a brief time, and disappear as the percentage of serum antibodies increases. This evolutionary pattern in turn suggests that the fecal antibodies have a local origin.

6043 HISTOCOMPATIBILITY ANTIGENS AND DERMATITIS HERPETIFORMIS WITH SPECIAL REFERENCE TO JEJUNAL ABNORMALITIES AND ACETYLATOR PHENOTYPE.

(Eng.) Reunala, T.; Salo, O. P.; Tiilikainen, A.; Mattila, M. J. (Univ. Central Hosp., Helsinki, Finland). *Br. J. Dermatol.* 94(2):139-143; 1976.

Studies were carried out in 61 patients with dermatitis herpetiformis in an effort to correlate the presence of various histocompatibility (HL-A) antigens with jejunal abnormalities and with the rate of acetylation of dapsone (4,4'-sulfonyldianiline). Among these patients, there was a significantly greater frequency of HL-A1 (64%) and of HL-A8 (87%) than in controls (17%, 55 controls had HL-A1 and 57 controls had HL-A8). HL-A1 was never detected in an HL-A8-negative subject. Of the 51 patients on whom jejunal biopsy was performed, 39 showed abnormal results; 35 of these patients had HL-A8. Of the 12 patients in whom the jejunal biopsy was normal, HL-A8 was present in 10, indicating that its frequency did not differ significantly in patients with normal and abnormal biopsies. There was no significant difference in the occurrence of various HL-A antigens when compared with the rate of acetylation. The incidence of HL-A8 among patients with dermatitis herpetiformis is higher than that reported earlier for such patients, and is similar to that reported for patients with adult celiac disease. The increased incidence of HL-A1 was atrributed to the increased frequency of the haplotype HL-A1, 8.

6044 GASTROINTESTINAL CHANGES IN HYPOGAMMAGLOBULINEMIA.

(Pol.) Horoszek-Maziarz, S.; Kryszewski, A.; Lehman-Borowska, J.; Rynkiewicz, H.; Bardzik, I.; Krupa-Wojciechowska, B. (I Clinic Internal Diseases, Inst. Internal Diseases Medical Acad., Gdansk, Poland). *Pol. Tyg. Lek.* 30(21):885-888; 1975.

Three cases of primary hypogammaglobulinemia are presented. Gammaglobulin levels were determined by paper electrophoresis, and the individual fractions of immunoglobulins were evaluated by immunoelectrophoresis. In all three cases, common symptoms were noted: the appearance of pneumonia several years before the full development of hypogammaglobulinemia; prolonged periods of diarrhea and symptoms of gastritis; poor absorption of vitamin B_{12} by the intestines; the absence of immunoglobulin A (IgA) and the absence or a decreased level of other IgG and IgM; and an increase in the bacterial population of the small intestine. All of the observed gastrointestinal disorders, as well as the infectious processes occurring during primary hypogammaglobulinemia, were attributed to the absence or decreased level of immunoglobulins, especially of IgA, which leads to structural and functional damage of the gastrointestinal tract and to damage of the entire immunological defense mechanism of the body.

6045 PEUTZ-JEGHERS SYNDROME. (Pol.) Bober-Dumanska, J. (V Clinic, Dept. Internal Diseases, Inst. Undergraduate Study, WAM, Warsaw, Poland). *Wiad. Lek.* 28(8):685-689; 1975.

The case of a 51-yr-old man with the Peutz-Jeghers syndrome coexisting with penile carcinoma is described. The patient presented with abdominal pain, lack of appetite, and an elevated temperature. During a 13-yr period, he had been hospitalized several times with polyps of the large intestine, attributed to the Peutz-Jeghers syndrome. Six years previously, he had been hospitalized for removal of a penile node, which was histologically described as planoepithelial carcinoma. At hospitalization, the patient showed signs of a somewhat enlarged liver and the beginning of inflammation of the gallbladder and possibly of the biliary ducts. Numerous polyps of various sizes were seen in the colon and rectum. As a preventive measure, therapy with 5-fluorouracil was begun, but was terminated after 1 month due to patient intolerance. Anemia and jaundice developed, and the elevated temperature persisted, despite treatment with antibiotics. Hematemesis and hematochezia developed. The patient died 82 days after hospitalization of massive hemorrhage from malignant gastric polyps. This case further confirms the precancerous nature of the Peutz-Jeghers syndrome.

6046 CELLULAR IMMUNOREACTIONS AGAINST COMMON ANTIGEN AND HUMAN LARGE OR SMALL INTESTINE ANTIGENS IN PATIENTS WITH REGIONAL ENTERITIS, ULCERATIVE COLITIS AND LIVER CIRRHOSIS. (Ger.) Eckhardt, R.; Heinisch, M.; Meyer zum Buschenfelde, K. H. (II Med. Klinik, Johannes-Gutenberg-Universitat, Mainz, W. Germany). *Z. Gastroenterol.* 13(3):413-417; 1975.

The leukocyte migration inhibition test (MIT) was used to examine cellular immunity in 27 patients with ulcerative colitis, 34 with Crohn's disease, 25 with cirrhosis, and 27 healthy controls. When tested against large intestine antigen, 96% of the patients with ulcerative colitis and 79% of the patients with cirrhosis displayed a migration index of less than 0.728, the lower limit of the 95% confidence interval for the control group. Only 19% of the patients with Crohn's disease fell below this value, while another 4 patients were in the borderline range. In the tests with small intestine antigen, migration indices below the lower limit of the 95% confidence interval for the controls (0.785) were found in 88% of the ulcerative colitis patients and 75% of those with cirrhosis. Only 32% of the patients with Crohn's disease fell below this value. In the tests with common antigen, 73% of the ulcerative colitis patients, 64% of the liver cirrhosis patients, and 21% of the Crohn's disease patients had migration indices below 0.6367, the lower limit of the 95% confidence interval for the controls. These findings may be used as an aid in differential diagnosis between ulcerative colitis and Crohn's disease, and they indicate that basically, only a weak immune tolerance exists toward intestinal antigens.

6047 GASTRIC FUNCTION IN CHRONIC RENAL FAILURE: EFFECTS OF MAINTENANCE HAEMODIALYSIS. (Eng.) McConnell, J. B.; Thjodleifsson, B.; Stewart, W. K.; Wormsley, K. G. (Dept. Medicine, Univ. Dundee, Dundee, Scotland). *Lancet* 2(7945):1121-1123; 1975.

Forty patients with chronic renal failure were studied to determine why some patients with azotemia have been reported to secrete abnormally large amount of acid and some to secrete very little. Fifteen patients were undergoing regular hemodialysis, while the remaining 25 patients were not. Ten nonhemodialysis patients had peak acid concentrations of less than 100 mM. The peak acid concentration values (range, 0-145 mM; median, 121 mM) of these patients were significantly less than the values of the hemodialysis patients (range, 109-148 mM; median, 128 mM). The peak acid outputs of the nonhemodialysis patients (range, 0-64.0 mmol/hr; median, 19.0 mmol/hr) were also significantly less than the outputs of the patients receiving hemodialysis (range, 10.7-54.6 mmol/hr; median, 37.0 mmol/hr). In four patients who had not previously been on hemodialysis, a significant increase in the mean peak acid concentration occurred within 5 months after the initiation of dialysis. The gastric secretory response to pentagastrin increased progressively during the course of hemodialysis, so that the 5- and 9-month values were significantly greater than before the start of hemodialysis. These studies show that many patients with chronic renal failure suffer from gastric mucosal hypofunction. Regular hemodialysis, by removing factors responsible for the gastric mucosal damage, permits manifestation of an underlying gastric hypersecretory state.

6048 DOSE-RESPONSE CURVES WITH METIAMIDE IN ZOLLINGER-ELLISON SYNDROME. (Fre.) Mignon, M.; Galmiche, J.-P.; Bonfils, S. (Hopital Bichat, 170, Boulevard Ney, F 75877 Paris Cedex 18). *Biol. Gastroenterol.* 8(3):239-244; 1975.

The interaction of metiamide (inhibitor of histamine-H_2 receptors) and pentagastrin on the acid and pepsin secretions of the stomach was studied in a 51-yr-old woman with Zollinger-Ellison's syndrome. Oral doses of metiamide (300, 600, or 1,200 mg) were administere on separate days, 1 hr before measuring the gastric reponse to increasing doses (0.25, 1.2, 5, and 12.5 μg/kg/hr) of pentagastrin administered by i.v. perfusion. Results were compared to the dose-respons curve of pentagastrin without metiamide. Metiamide reduced basal gastric acid and pepsin secretions; the effect was dose-dependent. The kinetic characteristics of the inhibition suggest a competitive metiamide-pentagastrin interaction for acid secretion and a noncompetitive interaction for pepsin secretion

GENERAL

Parasitology

6099 INTESTINAL BILHARZIASIS IN GUADELOUPE. (Fre.) Tribouley, J.; Tribouley-Duret, J.; Bernard, D.; Appriou, M.; Pautrizel, R. (Laboratoire d'Immunologie et de Biologie parasitaire, Universite de Bordeaux II, 33-Bordeaux, France). *Bull. Soc. Pathol. Exot.* 68(2):180-193; 1975.

Endemic intestinal bilharziasis in Guadeloupe was studied by testing sera from 8,500 persons for the presence of antibodies to *Schistosoma mansoni*. Antigen was prepared from a stock of *S. mansoni* originating in Puerto Rico, and was maintained in the laboratory in either mouse or hamster hosts. The parasites were crushed in a mortar and treated successively with ethanol at -20 C and ether anhydride. After centrifugation, the precipitate was dried, and the last traces of ether were eliminated. The powder was resuspended and adjusted for pH; a supernatant from a final centrifugation constituted the antigenic solution. The serum antibody-antigen reaction was carried out in the presence of guinea pig complement using an automated microtechnique. The immunologic method used in this study was a sensitive indicator of endemic levels, since an average of 35% of the population had positive sera, compared to the 8% reported by parasitological methods. Percentages of positive sera in different regions varied from 13 to 78%, which may be explained by population density and proximity and by the use of infested rivers. The age group with the highest endemic level was 30-40 yr, with 65% demonstrating positive sera. Sera was positive in less than 30% of the 0-10 yr age group, and percentages tended to diminish in the population over 40 yr. The diminution of positive responses may be a result of a change in the immunological response of the individual to an antigenic stimulus of prolonged duration.

6100 THE INTENSITY AND EFFECTS OF INFECTION WITH Schistosoma mansoni IN A RURAL COMMUNITY IN NORTHEAST BRAZIL. (Eng.) Lehman, J. S.; Mott, K. E.; Morrow, R. H., Jr.; Muniz, T. M.; Boyer, M. H. (Edna McConnell Clark Foundation, 250 Park Ave., New York, NY 10017). *Am. J. Trop. Med. Hyg.* 25(2):285-294; 1976.

The intensity of infection with *Schistosoma mansoni* and its effects were investigated in a defined population living in three contiguous subcounties in a nonmalarious area of northeastern Brazil. Quantitative stool egg counts were performed on 363 of the 417 inhabitants; physical examinations were performed on 294 of the 357 individuals over 5 yr of age. The maximum increase in incidence was observed between the 1-4 yr (36%) and 5-9 yr (72.6%) age groups, and the maximum increase in the fecal egg count occurred between 5-9 yr (132 eggs/ml) and 10-14 yr (301 eggs/ml) age groups. By age 20, almost everyone was infected. Relatively high geometric mean egg counts (>100 eggs/ml) were found in persons from under age 5 to about 34 yr. In the subcounty with the lowest quantitative egg counts, the age-specific prevalence rates increased more slowly than in the subcounties with higher egg counts. Nearly 50% of the total fecal egg output was accounted for by 22 individuals, with a mean age of 12.6 yr; egg counts were all over 800 eggs/ml of stool, with a mean of 1,514 eggs/ml. In children aged 10-14 yr, 85.4% had hepatomegaly; in all other age groups, the percentage ranged from 60.4 to 66.7%. In children aged 5-9 yr, 7.5% had splenomegaly, while the percentage ranged between 15.4 and 20.8% in the other age groups. The degree of hepatomegaly was directly correlated with increasing egg counts ($p<0.01$). This was not true for adults, nor was there an overall difference between infected and noninfected adults with respect to liver and spleen enlargement ($p>0.1$). In children, neither the presence of infection with *S. mansoni* nor its intensity was reflected by altered anthropometric measurements. The results support the argument for identification and selective and preventive chemotherapy of children with high egg counts.

GENERAL

Regional Enteritis

6118 CRITICAL STUDY OF THE EFFECTS OF ANTI-TUBERCULOSIS MEDICATION IN 18 PATIENTS WITH SEVERE FORMS OF CROHN'S DISEASE. (Fre.) Paris, J.; Paris, J. C.; Simon, V. (C.H.U., Lille, France). *Lille Med.* 20(4):333-338; 1975.

A series of 18 patients (10 men and 8 women, aged 16-47 yr) with severe Crohn's disease were treated with antitubercular drugs in combinations of three. Drugs used were: streptomycin, 1 g/day, i.m.; rifampicin, 600 mg/day, p.o.; ethambutol, 1,200 mg/day, p.o.; and isoniazide, 450 mg/day, p.o. Hepatitis attributed to the rifampicin developed in five patients. Three cases are reported in detail. There were no deaths and no amyloidosis or extradigestive lesions. Spread of disease to other intestinal segments was prevented as no ileocolitis developed in the four patients with ileitis. General state of health improved in 15 cases with weight gain in 16 and complete disappearance of functional symptoms in 11. X-ray studies demonstrated stabilization of disease in 3 patients, improvement in 10, and no evidence of disease in 3 patients treated for less than 6 months. Surgery was performed in three cases either because lesions persisted or complications arose (intestinal hemorrhage and ileocecal sclerosis). Treatment eradicated five disease-related and two surgery-related fistulas. The lesions of Crohn's disease and tuberculosis are histologically similar, which may explain the efficacy of the drugs studied.

6119 A CASE-CONTROL METHOD FOR SEEKING EVIDENCE OF CONTAGION IN CROHN'S DISEASE. (Eng.) Miller, D. S.; Keighley, A.; Smith, P. G.; Hughes, A. O.; Langman, M. J. S. (Medical Sch., Nottingham Univ., Nottingham, England). *Gastroenterology* 71(3): 385-387; 1976.

A case-control study was undertaken in 103 patients with Crohn's disease to ascertain whether this disease is contagious. All patients were diagnosed between 1958 and 1973. The addresses of all places of residence, schooling, and employment from 5 yr before the onset of symptoms until December 31, 1972 or death were determined. For each patient, two controls, matched by age (to within 1 yr), sex, and domicile to within ¼ mile, were selected. The application of the Pike and Smith case control technique for evaluating clustering of patients in time and space failed to reveal any significant clustering of patients indicative of contagion. Unless Crohn's disease is a rare response to a common infection, it appears that the disease is not contagious.

6120 AN ATTEMPTED EXPERIMENTAL REPRODUCTION OF THE HISTOGENESIS OF CROHN'S DISEASE. NOTE I: PRODUCTION OF A LASTING INTESTINAL LYMPHATIC BLOCK BY AN ORIGINAL TECHNIQUE. (Ita.) Pace, M.; Cardona, G.; Cataliotti, L.; Brugnola, D.; Pirillo, M.; Bandettini, L.; Nannelli, A. (Clinica II, Univ. di Firenze, Florence, Italy). *Acta Chir. Ital.* 30(4):455-469; 1974.

A new method of producing a lymphatic block in the small intestine was tested on 16 dogs; it consists of lymphangiofluoroscopic visualization of the lymphatic ducts and their multiple ligation at the level of the mesentery to achieve a complete and lasting block. Results show there are advantages compared to other methods (ligation, adenectomy, sclerosing injection, resection of the soft parts, and autograft). The numerous ligations make it possible to achieve a block lasting over a year. The method permits alterations of intestinal loops attributed to lymphostasis.

6121 AN ATTEMPTED EXPERIMENTAL REPRODUCTION OF THE HISTOGENESIS OF CROHN'S DISEASE. NOTE II: HISTOPATHOLOGICAL ASPECTS OF LASTING SEGMENTARY LYMPHATIC BLOCK OF THE ILEUM. (Ita.) Pace, M.; Cardona, G.; Cataliotti, L.; Brugnola, D.; Pirillo, M.; Nannelli, A.; Bandettini, L. (Clinica II, Univ. di Firenze, Florence, Italy) *Acta. Chir. Ital.* 30(4):471-489; 1974.

A lasting lymphatic block of the ileum was produced in 17 dogs by lymphangiofluoroscopic visualization of the lymphatic ducts and multiple ligation of the mesenteric lymphatic vessels. Anatomopathological results showed the direct effects of lymphostasis and other phenomena, such as ulcerations of the mucous membrane, segmentary stenoses, hyperplasia and increase in follicular aggregations, and polymorphic cellular infiltrations diffused under the mucous membrane. The findings confirm the importance of lymphostasis in the morphogenesis of Crohn's disease.

6122 ENDOSCOPIC RESULTS IN FIVE PATIENTS WITH CROHN'S DISEASE OF THE ESOPHAGUS. (Eng.) Huchzermeyer, H.; Paul, F.; Seifert, E.; Frohlich, H.; Rasmussen, Ch. W. (Medical Sch. Hannover, Hanover, W. Germany). *Endoscopy* 8(2):75-81; 1976.

The endoscopic and radiographic appearances of the esophagus in Crohn's disease were studied in five cases. Two stages of the disease were differentiated: a nonstenosed phase predominated by inflammation and a phase of increasing stenosis with a predominant symptom of dysphagia. The morphological changes were mainly in the middle and lower parts of the esophagus. In one of the two patients in stage 1, endoscopy showed erosions and granulomatous changes in the lower esophagus. X-ray showed an irregularity of the esophageal wall. In the second patient, endoscopy showed flat ulcerations, erosions, and granulomatous and polypoid changes over the entire esophagus. A cobblestone picture in the middle and lower esophagus was seen by x-ray. In the first of the three patients with stage 2 disease, endoscopy showed stenosis 29 cm from the incisors, with narrowing to pencil thickness. Proximal to this, the mucosa was hyperemic, with a white fibrin and mucous covering, which was vulnerable to the touch. X-ray showed tubular stenosis with an irregular contour, as it did in the two remaining cases. In the second of these, endoscopy revealed a tumor-like process 35 cm below the tooth line. In the last case, endoscopy showed a thread-like stenosis 34 cm from the incisors. Proximal to it, the mucosa showed shallow ulcers covered with fibrin. Neither endoscopy, radiology, nor guided biopsy was sufficient to diagnose Crohn's disease. Exact diagnosis was possible only by histological examination of a resected specimen.

6123 CALCIUM ABSORPTION IN CROHN'S DISEASE. (Eng.) Krawitt, E. L.; Beeken, W. L.; Janney, C. D. (Dept. Medicine, Univ. Vermont, Burlington, VT). *Gastroenterology* 71(2):251-254; 1976.

Calcium balance, endogenous loss of calcium, and intestinal absorption were measured in 31 patients with Crohn's disease, using a simultaneous metabolic balance and calcium isotope regimen. Calcium malabsorption resulting in negative calcium balance was found in only four patients. No elevation of endogenous fecal calcium or total secreted intestinal calcium was observed in 10 patients, regardless of the level of net or true calcium absorption. A nonlinear correlation between calcium balance and serum protein loss was observed, but no association with intestinal fat excretion, *d*-xylose absorption, bacterial colonization of the jejunum, or glucocorticosteroid therapy was noted. The results indicate that in this group of patients, calcium malabsorption occurred infrequently, and that the levels of calcium excretion correlated best with enteric protein loss.

6124 CONTRIBUTION TO THE COINCIDENTAL OCCURRENCE OF REGIONAL GRANULOMATOUS ENTERITIS AND IDIOPATHIC RECTOCOLITIS. (Rus.) Vrubel, F.; Martinek, K. (First Surgical Clinic, J. E. Purkinje Univ., Brno, Czechoslovakia). *Scr. Med. (Brno)* 48(6/7):531-536; 1975.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-31
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

LIBRARY U. OF I.

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1978.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

sec	second(s)
SGOT	serum glutamic-oxalacetic transaminase
SGPT	serum glutamic-pyruvic transaminase
U	unit(s)
UV	ultraviolet
V	volt
WBC	white blood cells (leukocytes), white blood count
yr	year(s)

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

6129 HISTOCHEMICAL CHANGES INDUCED BY TRUNCAL VAGOTOMY IN DIFFERENT SEGMENTS OF THE DIGESTIVE TRACT. (Ger.) Ihasz, M.; Ungvary, Gy.; Koiss, I.; Hudak, A. (II. Chirurgische Klinik, Medizinische Universitat Semmelweis, Budapest, Hungary). *Z. Exp. Chir.* 7(5):273-289; 1974.

Histochemical changes in various segments of the gastrointestinal tract after truncal vagotomy were studied in dogs. The animals received midline laparotomies; the anterior and posterior vagus branches were mobilized subdiaphragmatically, and 2-3 cm of nerve was resected. Completeness of the vagotomy was confirmed histologically. At various postvagotomy times, gastric, duodenal, jejunal, ileal, and colon sections were prepared. Alkaline phosphatase (AKP) increased negligibly in most gastric sections, mainly in the intermediate space between the glandular fundus and the lamina muscularis mucosae; epithelial glandular cells were negative. Acid phosphatase (ACP) increased in the glandular cells, which were normalized in 2 weeks. Succinodehydrogenase (SDH) was initially reduced, but normalized in 6 months. In the duodenum, AKP initially increased, then decreased while ACP initially decreased, then increased, both by week 4. SDH rose after week 4. In the jejunum, there was no AKP change in the tunica mucosa until a decrease at week 4. There was also a decline in the cuticles of villous epithelium and a 50% increase in the glandular epithelium of the Lieberkuhn's crypts during week 1. Nonspecific esterase (NSE) did not change, but SDH decreased from day 2 to week 4. ACP increased by day 2-3, then decreased through week 4. In the ileum, both AKP and ACP initially increased, then decreased, while NSE failed to change, and SDH declined. AKP remained unchanged in the colon up to day 10, then decreased; ACP initially increased, then declined, and SDH did not change. Truncal vagotomy probably does not elicit histochemical changes in the gastrointestinal tract, which could explain postvagotomy problems.

6130 EFFECT OF HYPOXIA ON RETICULAR FIBERS IN RAT LIVER. (Ger.) Baranova, M.; Meitner, E. R.; Trskova-Boselova, L. (Medical Faculty, Comenius Univ., Martin, Czechoslovakia). *Anat. Anz.* 137:503-511; 1975.

Based on accumulating evidence that oxygen deficit is a stimulus to connective tissue formation, the effect of hypoxia on the reticular fiber (RF) framework in 12 pregnant Wistar rats was examined. The animals were exposed to 60-min hypoxic intervals daily for 21 days, and maternal and neonatal liver probes were analyzed. In adults, the RF between the liver plates and along the bile ducts and peripheral vascularization was enlarged and thickened. Long strands penetrated into the parenchyma, extending in a continuous sheet between vessels. Shorter stretches of RF appeared in large coil formations between the plates, usually around hemina. Evidence of inflammation and the presence of fibroblasts were never seen. In newborns, a picture similar to hypoxic adults was found, with bizarre formations of thickened fibers. Unlike the adult or control neonates, the parenchyma was little differentiated, a stigma which was more extensive, and probably more critical, than the RF plethora. The morphological findings are interpreted as an initial stage of the changes of hepatic connective tissue, which lead to fibrosis after prolonged and nonintermittent hypoxia.

ABSORPTION - EXCRETION - TRANSPORT

6142 MONOSACCHARIDE-DEPENDENT K^+-INFLUX ACROSS THE MICROVILLOUS MEMBRANE OF RAT JEJUNUM. (Ger.) Remke, H.; Luppa, D.; Muller, F. (Physiologisch-Chemisches Institut, Karl-Marx-Universitat, 701 Leipzig, E. Germany). *Acta Biol. Med. Ger.* 34(10):1567-1572; 1975.

Na^+ and K^+ influx across villous membranes were studied during the initial phase of monosaccharide (MS) transport. Paired comparisons of rat jejunum preparations, incubated with labeled ions, were related to steady state data. After incubation with Na^+-dependent sugars (D-galactose and methyl-α-D-glycoside), the K^+ influx fell. L-arabinose and L-sorbose, which are Na^+-independent, had no effect, but Na^+-dependent D-glucose and Na^+-independent D-fructose increased K^+ influx, because both MS are metabolizable. When the mucosal surface was exposed to the MS only during the time required for tracer measurement (maximum 50 sec), D-glucose behaved as a Na^+-dependent sugar, but D-fructose had no unambiguous effect on either ion. Since both ion influxes are not only affected by MS membrane transport (K^+ inhibition and Na^+ stimulation), but also by MS metabolism (K^+ stimulation and Na^+ inhibition), direct involvement of ($Na^+ + K^+$)-ATPase in MS transport across the membrane is inferred. An ATPase regulatory system had previously been demonstrated in the brush border. The hypothesis explains the changes in K^+ influx which the conventional gradient hypothesis omits.

6143 EFFECT OF CHOLESTASIS AND BILIARY DIVERSION ON THE ABSORPTION OF Na OCTANOATE IN THE RAT. (Eng.) Laurendeau, G.; Roy, C. C. (Hopital Sainte-Justine, Univ. Montreal, 3175 chemin Sainte-Catherine, Montreal H3T 1C5, Quebec, Canada). *Experientia* 32(1):75-77; 1976.

Having shown previously that the absorption of an actively transported substrate (3-*O*-methyl glucose) is increased following a 48-hr period of biliary diversion and impaired after a comparable period of cholestasis, the present study was carried out to determine if the absorption of octanoate, a passively transported molecule and the main constituent fatty acid of medium chain triglycerides, is similarly affected. Following the creation of a bile fistula, common bile duct ligation, or a sham-operation, male Sprague-Dawley rats received intraduodenally a mixture of 2% casein hydrolysate, 3% Na caseinate, and 13% dextrimaltose in an electrolyte solution containing 35 and 9 mEq/1 of Na and K, resp. After 48 hr, the absorption of Na octanoate was studied in 20-cm segments of proximal jejunum perfused *in vivo* with 11 mM Na octanoate, 3.6 µCi of Na octanoate-1-^{14}C, and 8.4 µCi of ^{3}H-labeled dextran. Although the mean rate of the disappearance of octanoate from the lumen of jejunal segments taken from the cholestatic animals (12.6 µM) and from the animals with bile duct diversion (13.2 µM) was lower than in controls (15.6 µM), this difference was not statistically significant. Although more Na was absorbed in bile fistula animals (313 µEq) than in the animals with bile duct ligation (163 µEq) or the controls (233 µEq), the difference with the bile-ligated rats was the only one to reach statistical significance ($p<0.01$). The ^{14}C radioactivity in portal plasma was usually over twice that found in aortic plasma, and accounted for approximately two-thirds of the counts absorbed over the 60-min experimental period. At the end of the perfusion, the ^{14}C uptake by jejunal segments represented less than 10% of the octanoate radioactivity that had disappeared from the lumen. No difference could be found between the three groups for tissue uptake and net portal transport. It is concluded that extrusion from the enterocytes and subsequent transport were unaffected by biliary diversion and by experimental cholestasis.

MOTILITY

6152 MATHEMATICAL MODELING OF THE COLORECTAL MYOELECTRICAL ACTIVITY IN HUMANS. (Eng.) Linkens, D. A.; Taylor, I.; Duthie, H. L. (Dept. Control Engineering, Univ. Sheffield, Sheffield, England). *IEEE Trans. Biomed. Eng.* 23(2):101-110; 1976.

Colonic myoelectrical activity was measured from the rectosigmoid in 66 human subjects, and three different mathematical models were constructed to simulate the myoelectrical patterns observed. Three basic patterns of behavior in colorectal myoelectrical activity were observed: a higher frequency rhythm (0.1-0.15 Hz), which was predominant throughout the rectum and lower sigmoid; a lower frequency rhythm (0.04-0.07 Hz); and periods of zero slow wave electrical activity. Linked relaxation oscillators were employed to simulate these myoelectrical patterns using three different mathematical models. In the three models, two of the activity patterns were obtained as stable limit cycle solutions produced by symmetrically coupling together two relaxation oscillators. The first model comprised a ring of interconnected oscillators, which produced a third stable solution representing the higher frequency of oscillation. Summation of adjacent oscillator outputs reproduced the zero activity when the oscillators were in antiphase. By the addition of an extra coefficient into the basic relaxation oscillator equation for the second model, the zero state of activity became a stable condition, and the three patterns of electrical activity were obtained without the necessity of a ring structure. The third model required a permanent parameter change to the basic Van der Pol equation to allow for the lower and higher frequencies to decay away to the zero activity condition. The two basic frequencies in colorectal myoelectrical activity that were measured can be reproduced by coupling together similar oscillators, rather than by postulating the existence of two separate types of cells having widely different intrinsic frequencies.

6153 ELECTRICAL OFF RESPONSE OF CAT ESOPHAGEAL SMOOTH MUSCLE: AN ANALOG SIMULATION. (Eng.) Chan, W. W.-L.; Diamant, N. E. (Toronto Western Hosp., Toronto, Ontario, Canada). *Am. J. Physiol.* 230(1):233-238; 1976.

The slow membrane depolarization, or "electrical off-response," that follows the electrical stimulation of cat circular esophageal smooth muscle was studied. Transverse strips of circular esophageal smooth muscle were obtained from 45 adult cats and were stimulated by trains of square-wave pulses (0.5-1 msec) delivered at a potential of 100 volts and a frequency of 10 cycles/sec. The pulsed current was administered by external platinum wire electrodes placed on either side of the muscle strips. The electrical off-response was preceded by a hyperpolarization of the muscle membrane, which was recorded during stimulation. The amplitude of the off-response depolarization increased directly with increasing amplitude of the preceding hyperpolarization. The membrane potential showed varying degrees of oscillation around the resting point, and the oscillation period was constant for a period (4-5 sec) that was double the time interval from the point of maximum hyperpolarization to the peak of the electrical off-response. These characteristics suggest that the electrical off-response could be represented by a linear second-order differential equation with variable damping. The application of this equation as an explanation for the observed bioelectrical events implies that the off-response depolarization is primarily a passive oscillation, as opposed to the active relaxation oscillations proposed to explain the electrical slow waves of the stomach, small intestine, and colonic smooth muscle. An analog simulation model based on this equation was constructed; and by varying the damping ratio and/or the natural frequency of the model, the characteristics of the electrical off-response of esophageal muscle were reproduced. The model provides a means of exploring the behavior of esophageal smooth muscle contractions under normal and pathological conditions.

6154 SMALL BOWEL MOTILITY: COMPARISON OF THE EFFECTS OF AN ANTICHOLINERGIC AGENT, THIS AGENT PLUS A TRANQUILIZER, AND A PLACEBO.

(Eng.) Rider, J. A. (Ralph K. Davies Medical Center, San Francisco, CA). *Curr. Ther. Res.* 20(2):142-148; 1976.

The effects of tridihexethyl chloride (TDC) either alone or in combination with meprobamate (MP) on the small bowel motility of normal adult men were measured by means of a miniature pressure transducer, swallowed, and positioned in the duodenum. After a 30-min pressure baseline was recorded, TDC (50 mg), either alone or in combination with MP (800 mg), was administered p.o. Within the 1st hr after administration intraluminal pressures fell below baseline and remained there over the entire 4-hr test period. Decreases were also observed after the administration of a placebo, but the pressure reductions after drug administration were significantly greater. Among nine subjects receiving TDC alone, the adjusted mean intraluminal small bowel pressure for the 4-hr period was 426 cm, representing 58% of baseline. This was in contrast to a value of 694 cm after placebo administration, which amounted to 74% of the baseline pressure. Among 10 subjects receiving the combination of TDC and MP, the mean intraluminal small bowel pressure for the same period was 2,202 cm, which represented 60% of the baseline pressure; the corresponding value after placebo administration was 3,147 cm, amounting to 81% of the baseline value. These results are consistent with previous findings showing that anticholinergic agents inhibit motility in patients with active duodenal ulcers.

6155 ACTION OF Sr ON THE TONUS OF PYLORIC ANTRUM STRIP FROM RAT'S STOMACH, PARTICULARLY, IN RELATION TO Ca.

(Eng.) Shino, H. (Kobe Univ. Sch. Medicine, Kobe, Japan). *Kobe J. Med. Sci.* 21(3):89-95; 1975.

The mechanism of action of Sr on the tonus of a strip of rat pyloric antrum was investigated in relation to the mobilization of Ca. The tissue was suspended in a bath solution to which drug solutions (calcium chloride, strontium chloride, potassium chloride, yohimbine hydrochloride, and propranolol hydrochloride) were added by dropping. Sr (4-8 mM) induced relaxation due to its membrane-stabilizing action in a normal solution, but initiated contraction in a high potassium (6 x 10^{-3} g/ml) depolarizing solution. In a calcium-bath solution, 2 mM of Sr released Ca from the membrane to elicit a contraction. This contraction gradually decreased, and finally disappeared with repeated applications of 4 mM Sr. Sr-induced contractions, due to the direct stimulation of contractile elements, remained constant in the high potassium (10^{-3} g/ml) depolarizing solution. Concentration-action curves of the contractions by exogenous Ca were prepared by the cumulative dose method. The log concentration-action curves of exogenous Ca in preparations in which the contraction by Sr had disappeared in the calcium-bath were shifted in parallel to the right by a low concentration (0.8 mM) of Sr, and were shifted to the right and downward by a higher concentration (8 mM) of Sr, corresponding to its competitive and noncompetitive antagonism, resp. In preparations in which the residual contraction by Sr (4 mM) had been obtained under high potassium depolarization in calcium-bath, Sr (0.8 mM and 8 mM) induced contractions and shifted the log concentration-action curve of exogenous Ca to correspond to the theory of competitive synergism between full agonist (Ca) and partial agonist (Sr). Since the direct stimulation of Sr to the contractile elements operates in this condition, the competitive synergism between Ca and Sr may occur in a reaction with troponin rather than in the membrane. This view is supported by the finding that 8 mM Sr did not exert noncompetitive inhibition against exogenous Ca in this condition, in striking contrast to the findings obtained in calcium-bath without high potassium depolarization.

6156 MOTOR AND BIOELECTRIC ACTIVITY OF CERTAIN SEGMENTS OF THE GASTROINTESTINAL TRACT OF DOGS DURING HEMORRHAGIC SHOCK.

(Ger.) Nikolov, N. A.; Dobrev, J.; Deleva, G. I.; Manolov, G. A. (Lehrstuhl fur Pathophysiologie, Medizinische Hochschule, 31 Sofia, Georgi-Sofijski-Str. 1, Bulgaria). *Zentralbl. Chir.* 100(24):1491-1497; 1975.

Small intestinal motility and bioelectric activity of stomach, duodenum, and upper jejunum were assayed in dogs in hemorrhagic shock. Small intestinal motility was reduced in 11/11 dogs at a blood pressure of 30 mm Hg. At 20 mm Hg, the tonic, rhythmic, and peristaltic motility was completely suppressed in 9/9 dogs. The bioelectric activity was also markedly reduced. At constant blood pressures under 40 mm Hg, both small intestinal motility and bioelectric activity were self-restored, with prominent spike potentials. Two hours after the onset of shock (blood pressure, 20 mm Hg), the intestinal loop was akinetic, and the bioelectric activity was strongly reduced. Blood reinfusion and 250 ml isotonic solution failed to normalize tonus, bioelectric activity, or blood pressure; small intestinal motility remained suppressed at least several days post-trauma. Hemorrhagic shock disturbed the rhythm of the slow gastric potential and depressed the amplitude of jejunal spike potential 80 min after the onset of bleeding. Two hours later, bioelectric activity was arrhythmic in the stomach and jejunum; by 3 hr, bioelectric activity was entirely absent, and the animals' condition was life-menacing. During this time, the mean femoral pressure was below 20 mm Hg.

SECRETION AND METABOLISM

Stomach

6172 MEASUREMENT OF GASTRIC FUNCTIONS DURING DIGESTION OF ORDINARY SOLID MEALS IN MAN. (Eng.) Malagelada, J.-R.; Longstreth, G. F.; Summerskill, W. H. J.; Go, V. L. W. (Mayo Clinic, Rochester, MN 55901). *Gastroenterology* 70(2):203-210; 1976.

A method for measuring gastric secretions and emptying rates during the digestion of ordinary (solid-liquid) meals in man is described. The technique quantifies movements of volume across the pylorus, using constant duodenal perfusion with a nonabsorbable marker, polyethylene glycol (PEG, 5 g/l), which in turn quantifies emptying into the duodenum of ^{14}carbon-labeled PEG (30 μCi). In practice, the subject swallows a single-lumen gastric tube and a triple-lumen duodenal tube; the former is used for sampling the postprandial gastric contents and for determining concentrations of meal, marker, acid, and pepsin, while the latter is used for nonabsorbable marker perfusion, quantification of the second marker's passage, the aspiration of duodenal contents, and the facilitation of suction at the duodenal aspiration site. Measurements of gastric functions after meal ingestion were performed on six healthy volunteers. Despite little variation in the volume of gastric contents during the 1st hr, there were significant increases in the amount of gastric contents emptied into the duodenum. Initial rapid gastric emptying was followed by a steady decrease in the volume of gastric contents emptied into the duodenum until the end of the study. During the 1st hr, the volume of gastric juice secreted resembled the volume of meal emptied through the pylorus. The pH of the gastric contents after meal ingestion approximated 5.0, with a rapid fall to less than 3.0 occurring after 60 min, and to less than 2.0 after 2 hr. Pre- and postprandial acid concentrations increased after ingestion and reached a plateau of about 90 μEq/ml after the 2nd hr. Total gastric acid content also increased rapidly after eating, peaked earlier than acid concentration (at about 1 hr), remained stable for another hour, and then rapidly decreased as the stomach emptied. Gastric acid and pepsin outputs, like total secretory volume, were highest during the 1st hr after eating. Secretory activity fell to near control values 2 hr after meal ingestion. Changes in serum immunoreactive gastrin concentrations followed secretory outputs, increasing twofold during the hour after eating and then slowly decreasing while intragastric pH and gastric secretion also declined.

6173 THE ROLE OF CYCLIC ADENOSINE 3':5'-MONOPHOSPHATE AS "SECOND MESSENGER" IN GASTRIC ACID SECRETION. (Ger.) Domschke, W.; Domschke, S. (Medizinische Univ.-Klinik, D-8520 Erlangen, Krankenhausstrasse 12, W. Germany). *Klin. Wochenschr.* 53(18):841-846; 1975.

Based on a review of animal and human experimentation, the "second messenger" role of cyclic AMP (cAMP) in human and canine gastric secretion is questioned. Four criteria must be satisfied to confer an intracellular function in gastric secretion on cAMP. The intracellular elevation in cAMP must vary directly with the extracellular hormone concentration and occur more or less simultaneously with the physiological effect. Exogenous cAMP should elicit the same effect as the hormone itself, and the tissue response to the hormone should be potentiated by the addition of a phosphodiesterase inhibitor. It has been shown that the cAMP concentration in human gastric mucosa does not increase after maximal gastric secretion stimulation by pentagastrin; nor is there any elevation in patients with hypergastrinemia or its hyperchlorhydric equivalents. This outcome is not necessarily decisive, since pentagastrin and other gastric secretion stimuli also increase phosphodiesterase. Adenylcyclase was not increased and phosphodiesterase was not decreased on histamine stimulation of gastric mucosa in the dog. At least one of the criteria can be unequivocally satisfied in the rat, frog (*Necturus maculosus*), rabbit, and guinea pig either after histamine or gastrin (pentagastrin) challenge; however, some rabbits and guinea pigs fail to respond to all. An overview of published data suggests that species specificity is the determinant, and that intraspecies variation in gastric secretion remains unexplained.

6174 INFLUENCE OF β-ADRENORECEPTOR BLOCKADE ON THE BASAL SECRETION OF THE STOMACH. (Ger.)

Anschelewitsch, J.; Okun, K. (Therapeutische Hospital klinik, Medizinisches Institut, Riga, Bulv. Padomju 12, USSR). *Dtsch. Z. Verdau. Stoffwechselkr.* 35(1): 11-15; 1975.

The effect of β-adrenoblockade on gastric secretion variables in 31 gastrointestinal patients was compared with that in atropine and control groups. The patients received propranolol (4 mg, i.v.) at the start of the second hour of a 2-hr gastric secretion measurement. Propranolol induced a significant depression in basal gastric secretion ($p<0.01$), HCl ($p<0.05$), and proteolytic enzymes ($p<0.01$) of 25%-35%. The concentration of HCl and the total proteolytic activity was unaffected. Propranolol depression was even more pronounced in patients with high initial secretion: gastric secretion, 30% ($p<0.01$); HCl, 35% ($p<0.05$); proteolytic enzymes, 43% ($p<0.01$); HCl concentration, 25% ($p<0.05$); and proteolytic activity, 13% ($p<0.05$). The propranolol effect was approximately equivalent to that of 0.75 mg atropine for all variables except proteolytic activity and HCl concentration. In patients with low initial secretion, propranolol depressed only gastric secretion and proteolytic activity 18%-26% ($p<0.01$); atropine reduced gastric secretion, proteolytic activity, and HCl concentration. The outcome suggests that elevated basal gastric secretion is associated with greater intensity of β-adrenergic processes.

6175 RELEASE OF GASTRIN BY VAGAL STIMULATION IN THE ACID SECRETORY RESPONSE TO FOOD. (Eng.)

Hunt, D. R.; Forrest, A. P. M. (Welsh Natl. Sch. Medicine, Cardiff, Wales). *Ajebak* 54(2):181-189; 1976.

The effect of gastrin release by vagal stimulation on acid secretory response to food was studied in eight dogs (four with innervated and four with denervated pouches made from the fundus of the stomach). All of the dogs had an esophageal fistula. In dogs with denervated pouches, the mean acid outputs (in mM/4 hr) after p.o., tube, and sham feeding (standard meal of homogenized ox-heart) ranged from 0.81 ± 0.17 to 2.23 ± 0.65, 1.23 ± 0.22 to 2.46 ± 0.47, and 0.10 ± 0.02 to 0.26 ± 0.03, resp., before denervation of the pyloric antrum. The corresponding values for dogs with innervated pouches before antral denervation were 8.36 ± 0.80 to 12.86 ± 1.30, 5.05 ± 0.31 to 7.84 ± 1.40, and 0.50 ± 0.11 to 1.46 ± 0.31, resp. After antral denervation, the corresponding values (p.o., tube, and sham feeding) for dogs with denervated pouches were 1.74 ± 0.26 to 2.64 ± 0.44, 1.90 ± 0.45 to 2.37 ± 0.85, and 0.16 ± 0.03 to 0.31 ± 0.09, resp., while those for two dogs with innervated pouches who survived antral denervation were 6.54 ± 0.37 to 9.91 ± 0.56, 4.30 ± 0.38 to 7.09 ± 0.28, and 1.39 ± 0.14 to 2.09 ± 0.16, resp. Only three dogs with denervated pouches survived antral denervation. If vagal release of gastrin were important in dogs with denervated pouches, the acid secretory response to p.o. feeding (by virtue of the cephalic phase acting through an intact vagal nerve supply to the pyloric antrum) should have exceeded that achieved by tube feeding alone; however, the results showed that the acid secretory responses to p.o. and tube feeding were about the same. In dogs with innervated pouches, the response to p.o. feeding exceeded that of tube feeding. Denervation of the antrum did not decrease the sham response in either group of dogs. Moreover, no significant stimulation of acid secretion from denervated pouches could be demonstrated with sham feeding. Since an adequate secretory response was observed in dogs with innervated pouches, this observation cannot be attributed to an inadequate stimulus. Although the acid output after a normal meal (p.o. feeding) exceeded the sum of the acid outputs by separate vagal (sham feeding) and gastric (tube feeding) stimulation in dogs with innervated pouches, the findings indicate that this increased acid output does not appear to be attributable to the effect of gastrin released by vagal stimulation.

6176 RELEASE OF GASTRIC INHIBITORY POLYPEPTIDE: COMPARISON OF HYPEROSMOLAR CARBOHYDRATE SOLUTIONS AS STIMULI. (Eng.)

Martin, E. W., Jr.; Sirinek, K. R.; Crockett, S. E.; O'Dorisio, T.; Mazzaferri, E. L.; Thomford, N. R.; Cataland, S. (Ohio State Univ. Coll. Medicine, Columbus, OH). *Surg. Forum* 26:381-382; 1975.

Because previous studies have indicated that intraduodenal glucose is a potent stimulus for the release of endogenous gastric inhibitory polypeptide (GIP), the GIP response to a variety of carbohydrate solutions was compared in six dogs with Mann-Bollman fistulas. Both 10% (556 mOsm/l) and 20% (1,112 mOsm/l) glucose were potent stimuli for the release of GIP at 5-180 min after the introduodenal instillation of the solutions over a 10-min period; the mean responses ranged between 285 and 1,016 pg/ml. However, the GIP response to 20% glucose was significantly ($p<0.05$) greater at 15 min (1,016 pg/ml) than at 30 min (942 pg/ml). GIP release was not observed with hyperosmolar solutions of galactose (556 mOsm/l) or mannitol (1,112 mOsm/l). The results suggest that the response to glucose is dose-related and that duodenal osmoreceptors do not have a primary role in the physiologic release of endogenous GIP.

6177 INFLUENCE OF HISTAMINE H_2 RECEPTOR BLOCKERS ON THE BIOSYNTHESIS AND DECOMPOSITION OF HISTAMINE IN THE GASTRIC MUCOSA. (Ger.)

Femppel, J.; Maslinski, S.; Sewing, K. F. (No affiliation given). *Z. Gastroenterol.* 14(Suppl.):252; 1976.

The effect of the histamine H_2 receptor inhibitors, metiamide (MA) and cimetidine (CD), on histidine carboxylase activity and histamine methylation in gastric mucosa was studied. Histidine carboxylase activity was assayed fluorimetrically in rat gastric mucosa homogenates whose acid secretion had been stimulated for up to 90 min with pentagastrin (2.5 μg/kg/min), without and after pretreatment with metiamide (2.5 mg/kg). Ring methylation was assayed radiochromatographically in guinea pig gastric mucosa with and without pretreatment with three doses of cimetidine (25 mg/kg). Pentagastrin-induced acid secretion was inhibited by metiamide, but the histamine content of the gastric mucosa was unaffected, independent of treatment. Histidine carboxylase activity rose 30 min post-pentagastrin, exceeding 100% after 90 min. Metiamide blocked histidine carboxylase elevation completely. Pentagastrin had no effect on histamine ring methylation, which was increased by about 25% by cimetidine.

6178 HISTAMINE H_2-RECEPTOR ANTAGONISTS.

(Eng.) Sewing, K.-Fr. (Pharmakologisches Institut der Universitat Tubingen, Wilhelmstr. 56, D-7400 Tubingen, W. Germany). *Acta Hepatogastroenterol. (Stuttg.)* 23(3):221-226; 1976.

A general review of studies involving the action of histamine H_2-receptor antagonists and their therapeutic relevance to gastrointestinal tract disorders is presented. H_2-receptor antagonists are powerful blockers of gastric acid secretion stimulated by histamine, pentagastrin, and food, and have led to the discovery of a number of previously unknown H_2-receptor localizations, including five in the guinea pig intestine. The first histamine H_2-receptor antagonist discovered was burimamide; because of its poor absorption after p.o. administration, this receptor has fallen into disfavor in light of the discovery of metiamide, which has the same histamine H_2-receptor antagonist properties and is absorbed p.o. Metiamide has been shown to be effective in preventing the occurrence of ulcers produced by pentagastrin or histamine in cats and has been effective in man in reducing basal, stimulated, and nocturnal secretions in both healthy volunteers and duodenal ulcer patients. Another H_2-receptor antagonist, cimetidine, has gained interest because it is about as effective as metiamide in blocking H_2-receptors and is devoid of metiamide's agranulocytosis-producing properties. In two open trials, cimetidine has been useful in treating 11 patients with gastric ulcer and 19 patients with active duodenal ulceration. Gastric mucosal damage produced by acetyl-salicylic acid has also been shown to be prevented by cimetidine. It appears that histamine H_2-antagonists will be useful in the management of diseases in which mucosal damage of the upper gastrointestinal tract is the predominant feature.

6179 MECHANISM OF METIAMIDE INHIBITION OF GASTRIC ACID SECRETION.

(Eng.) Brown, B. N.; Charters, A. C., III.; Orloff, M. J. (Univ. California Sch. Medicine, La Jolla, CA). *Surg. Forum* 26:357-359; 1975.

The components of the cyclic AMP (cAMP) system during metiamide inhibition of acid secretion were examined in the isolated frog gastric mucosa to determine whether metiamide blocks this intracellular pathway. Metiamide (10^{-5} M) caused a significant inhibition of pentagastrin (10^{-5} M)-stimulated gastric acid secretion (44% of maximal stimulation, $p<0.05$). A 10-fold higher dose of metiamide caused a similar inhibitory effect (45% of maximal stimulation, $p<0.05$). The addition of 10^{-5} M metiamide to hypersecreting mucosae (>125 $m\mu Eq/cm^2/min$) also produced a significant inhibition of acid secretion (51%, $p<0.05$). The inhibition of acid secretion was not accompanied by a consistent pattern of change in cAMP concentration, adenyl cyclase activity, or phosphodiesterase activity. The higher dose of metiamide (10^{-4} M) and the addition of 10^{-5} M metiamide to the hypersecreting mucosae caused a greater increase in cAMP (2.73 pM/mg), than that in pentagastrin-stimulated mucosae (1.45 pM/mg) and mucosae incubated with 10^{-5} M metiamide and pentagastrin (1.76 pM/mg). Metiamide does not appear to inhibit acid secretion by blocking the formation of cAMP. The observed increase in cAMP levels accompanying the fall in acid secretion could be interpreted to suggest that metiamide blocks the effects of cAMP by interrupting the intracellular pathways at some later step. These results do not support the conclusion that metiamide blocks histamine stimulation of adenyl cyclase activity in a cell-free preparation of guinea pig gastric mucosa.

6180 THE EFFECT OF ACUTE HYPERGLYCEMIA ON MEAL-STIMULATED GASTRIC, BILIARY, AND PANCREATIC SECRETION, AND SERUM GASTRIN.

(Eng.) MacGregor, I. L.; Deveney, C.; Way, L. W.; Meyer, J. H. (Veterans Admin. Hosp., 4150 Clement St., San Francisco, CA 94121). *Gastroenterology* 70(2):197-202; 1976.

The effects of hyperglycemia on human pancreatic, biliary, and gastric secretory responses to meals were investigated. Following an overnight fast, seven normal healthy subjects took a 500-ml liquid test meal containing 38 g of corn oil and 63 g of nonfat milk powder (22 g protein and 33 g carbohydrate). Hyperglycemia was induced with a bolus injection of glucose (150 mg/kg, i.v.) followed by a glucose infusion (10 mg/kg/min, i.v.) that was continued throughout the 150-min duration of the study. A jejunal perfusion method was used to measure pancreatic outputs of trypsin and biliary outputs of bile salts and to indirectly quantify the amount of acid secreted by the stomach. Serum gastrins were also measured basally and at intervals after the meal. Data from six evaluable subjects showed that the glucose load suppressed gastric acid secretion in response to the test meal; this suppression was most marked in the first 60 postcibal min, coinciding with the period of most marked hyperglycemia. Total acid output for the 150-min test period was suppressed in five hyperglycemic subjects, with the mean value being 21.25 ± 3.58 mEq compared to a mean control value of 29.11 ± 4.32 mEq ($p<0.05$). Trypsin output was also reduced from a mean control level of 53,287 ± 5209 U to a level of 32,908 ± 6674 U in hyperglycemic subjects ($p<0.025$). Bile salt output was decreased from a mean control value of 3221 ± 340 mg to 1675 ± 350 mg in hyperglycemic individuals ($p<0.025$). The mean serum gastrin concentration was significantly reduced ($p<0.025$) only for 30-min samples; at this time the mean value for five evaluable hyperglycemic subjects was approximately 65 pg/ml, compared with a control value of about 90 pg/ml. Hyperglycemia, which is acutely induced by i.v. glucose infusions, has a variety of suppressive effects on the gastrointestinal function of normal subjects.

6181 IMPLICATIONS OF THE NEUTRAL CARRIER OF Cl^--HCO_3^- EXCHANGE MECHANISM IN GASTRIC MUCOSA. (Eng.) Rehm, W. S.; Sanders, S. S. (Univ. of Alabama in Birmingham, Medical Center, Birmingham, AL 35294). *Ann. N.Y. Acad. Sci.* 264:442-455; 1975.

SECRETION AND METABOLISM

Pancreas

6197 A NEW TECHNIQUE FOR THE STUDY OF THE EXOCRINE PANCREATIC SECRETION IN THE RAT. (Fre.) Roze, C.; De La Tour, J.; Chariot, J.; Souchard, M.; Debray, C. (Hopital Bichat, 170, boulevard Ney, F 75877 Paris Cedex 18, France). *Biol. Gastroenterol. (Paris)* 8(4):291-295; 1975.

The continuous perfusion of a diluting fluid has significantly improved the collection and determination of the main constituents of pancreatic fluid excreted from fistulized anesthetized Wistar rats. The determination of sodium excretion provided a good approximation of the amount of excreted pancreatic fluid. Bicarbonates were determined by Technicon autoanalysis and proteins by UV absorption or Lowry's method. The volume of pancreatic secretion increased slowly from about 7 hr after fistulization. Concentration of sodium remained stable in control rats, but rose sharply in response to 2.5 IU/kg/hr of secretin. Total protein excretion was elevated initially but fell rapidly and stabilized at 3-8 hr. The best time for observation of pancreatic excretion appears to be 4-8 hr following insertion of the fistula.

6198 IMMUNOLOGICAL STUDIES OF THE PANCREAS. (Ger.) Friemel, H.; Brock, J.; Schutt, C.; Zastrow, R.; Velbri, S. (Klinik fur Innere Medizin, Universitat Rostock, 25 Rostock, Leninallee 70, E. Germany). *Z. Gesamte Inn. Med.* 30(12): 415-419; 1975.

The first clinical results for demonstrating circulating pancreatic antigens are reported. Postmortem (5 hr) human pancreas and rabbit and horse antisera were used; blood samples were taken from patients with clinically confirmed acute or chronic pancreatitis. Zone electrophoresis of pancreatic extract identified organotypical proteins, and agar gel electrophoresis found one anodic and three cathodic fractions. Polyacrylamide disk electrophoresis showed at least 24 protein bands. At least seven immunologically unique pancreatic antigens, including albumin, α_1-antitrypsin, haptoglobin, transferrin, and immunoglobulins G (IgG) and A, were recovered in reacting human serum and pancreatic extract with nonabsorbed antipancreas immune serum. In reacting pancreatic extract with absorbed antiserum, 15 precipitation lines developed, whose electrophoretic mobility ranged between albumin and the slow IgG region. The Sephadex elution profile of human extract identified five serum-free fractions; fraction 5 was established as antigenic. Cell immunity against pancreatic antigen was demonstrated in several cases of chronic pancreatitis by lymphocyte transformation tests, and in several cases of acute pancreatitis, circulating pancreatic antigens were detectable.

6199 INTERACTION OF PORCINE VASOACTIVE INTESTINAL PEPTIDE WITH DISPERSED PANCREATIC ACINAR CELLS FROM THE GUINEA PIGS. STRUCTURAL REQUIREMENTS FOR EFFECTS OF VASOACTIVE INTESTINAL PEPTIDE AND SECRETIN ON CELLULAR ADENOSINE 3':5'-MONOPHOSPHATE. (Eng.) Robberecht, P.; Conlon, T. P.; Gardner, J. D. (Univ. Brussels Medical Sch., 1000 Brussels, Belgium). *J. Biol. Chem.* 251(15):4635-4639; 1976.

The effects of secretin and vasoactive intestinal peptide (VIP), as well as their respective analogs and fragments, on cellular cyclic AMP (cAMP) in dispersed pancreatic acinar cells from guinea pigs were investigated. Secretin appeared to interact with a single class of high-affinity receptors to produce a 10-fold increase in cellular cAMP, with the half-maximal stimulation occurring at a secretin concentration of 2×10^{-10} M. In contrast to secretin, the dose-response curve for VIP-stimulated cellular cAMP was biphasic and appeared to reflect the interaction of VIP with two functionally distinct classes of receptors. The interaction of VIP with a high-affinity class of receptors (half-maximal stimulation at 4 x 10^{-10} M VIP) produced a threefold increase in cellular cAMP, whereas the interaction of VIP with low-affinity receptors (half-maximal stimulation at 10^{-7} M) produced a sixfold increase in cellular cAMP. Studies with synthetic fragments of VIP and secretin indicated that the receptor having a high affinity for VIP has a low affinity for secretin and interacts with, but does not distinguish between, secretin, secretin 5-27, and [6-tyrosine]secretin or between secretin 14-27, VIP 14-28, and VIP 15-28; this high-affinity receptor for VIP increases cellular cAMP when occupied by VIP, but not when occupied by secretin, [6-tyrosine]secretin, or secretin 1-14. The receptor having a low affinity for VIP has a high affinity for secretin and interacts with and distinguishes between secretin, secretin 5-27, and [6-tyrosine]secretin; this low affinity receptor for VIP also interacts with secretin 14-27, but not with VIP 14-28 or VIP 15-28. It increases cellular cAMP when occupied by VIP, secretin, [6-tyrosine]-secretin, or secretin 1-14. Two receptors appear to mediate the stimulation of cAMP in dispersed guinea pig pancreatic acinar cells.

6200 PANCREATIC FUNCTION AFTER TRUNCAL VAGOTOMY: ANIMAL EXPERIMENTS ON PIGS AND RATS. (Ger.) Loeweneck, H.; Bruckner, W. L.; Maass, U.; Appel, G.; Schmidt, G. P. (Anatomisches Institut, Abtlg. fur experimentelle Morphologie, D-8 Munchen 2, Pettenkoferstrasse 11, W. Germany). *Z. Gastroenterol.* 13(4):457-463; 1975.

Blood sugar levels after glucose loading, changes in fasting blood sugar, variations in serum α-amylase, and islet modifications were investigated 3-10 weeks after truncal vagotomy (TV) in 52 Wistar rats and 17 pigs. Glucose tolerance tests (0.5 g/kg, i.v.) were performed on 5 vagotomized pigs and 12 controls. Fasting blood sugar was determined in 20 vagotomized rats after pyloroplasty and in 32 vagotomized rats without pyloroplasty. There were no significant differences in the blood sugar levels of vagotomized and control pigs after glucose loading. All vagotomized animals without pyloroplasty had pyloric stenosis. Even after 24 hr fasting, the stomachs were dilated and full. The fasting blood sugar level in vagotomized pigs and rats was 37% lower than in controls. After vagotomy the α-amylase concentration in fasting pigs rose from 1,429 U/I to 7,650 U/I; in vagotomized rats with pyloroplasty, the amylase level fell from 2,241 U/I to 1,751 U/I. A clustering of A-cells in the marginal zone of the islets of Langerhans was found 5 weeks postvagotomy; the mantel sometimes consisted of five cell rows. The A:B cell ratio was 1:1.4, somewhat lower than the normal 1:2.3. I.v. glucose loading responses in vagotomized pigs do not differ significantly from those of controls.

6201 EFFECT OF ACUTE IRRADIATION ON THE EXOCRINE SECRETION OF THE PANCREAS IN THE PIG. (Fre.) Corring, T.; Daburon, F.; Remy, J. (Centre National de la Recherche Zootechnique, I.N.R.A., 78350 Jouy-en-Josas, France). *Strahlentherapie* 149(4):417-425; 1975.

Exocrine pancreas secretion was studied in six castrated male pigs (Large White strain) 8 days prior to exposure to acute, partial irradiation and for 11 days after. Fistulas to the pancreatic duct and to the duodenum were created in the pigs, the first for extraction of fluids and the other for recirculation after analysis. Four animals received a postdiaphragmatic irradiation of 800 rads, and two others were subjected to 600 rads. Four samples of pancreatic juice were analyzed every 24 hr. After irradiation, the pigs' temperatures rose, and diarrhea was common; four pigs recovered, while two/four that had received 800 rads died. Regardless of dose, irradiation caused an immediate decrease in the volume of pancreatic secretion and in total enzymatic activity. The proteolytic enzyme (chymotrypsin and trypsin) levels remained unchanged while in each animal lipase levels decreased for the first 3 days and then increased until the 11th day, where they finally stabilized at 180-210% of the original concentration. Immediately after irradiation, amylase levels rose to 125% of their initial value and then returned to the preirradiation level. These results show a direct action of irradiation on the pancreas, either stimulatory or inhibitory. When secretin (1 IU/kg) was injected on the 5th day after irradiation the volume of pancreatic secretion increased immediately, suggesting a possible indirect action of radiation that affects the regulatory system. A feedback effect from the stomach is also possible.

6202 LATE EVOLUTION OF PROTEINS WATER AND BICARBONATE SECRETION IN THE DOG CHRONIC ALCOHOLIC PANCREATITIS [Abstract]. (Eng.) Tiscornia, O. M.; Sarles, H.; Palasciano, G. (INSERM U-31, 46, chemin de la Gaye, F-13009 Marseille, France). *Digestion* 13(3):188; 1975.

SECRETION AND METABOLISM

Hepatobiliary Tract

6207 METHOD FOR MEASURING HEPATIC UPTAKE OF OXYGEN OR OTHER BLOOD-BORNE SUBSTANCES IN SITU. (Eng.) Lautt, W. W. (Coll. Medicine, Univ. Saskatchewan, Saskatoon, Saskatchewan S7N 0W0, Canada). *J. Appl. Physiol.* 40(2):269-274; 1976.

An *in situ* method for the continuous recording of hepatic venous and arterial blood flow while measuring hepatic and splanchnic oxygen uptake in the intact liver of the cat is described. The total outflow of the liver is measured directly as it flows into an external reservoir by an electromagnetic flowmeter. Calibration does not interfere with the hepatic blood flow. The proportion of the hepatic artery flow is determined by a second electromagnetic flowmeter, and the *in situ* calibration of the flow probe is achieved by occluding the hepatic artery with a loop of thread and timing the rate of blood flow through a splenic arterial cannula. Oxygen uptake by the denervated liver in 13 splenectomized cats was 4.5 ± 0.3 ml/min/100 g, representing 54% of the total oxygen removed by the splanchnic bed. The metabolic state of the liver remained stable for at least 2 hr, during which an average of 29 1-ml blood samples were taken from 3 cats. The decrease in hematocrit was less than 3 U. The presence of an extracorporeal blood reservoir is important for repeated metabolic determinations, because equilibrated blood from the reservoir can be used for volume replacement. The method obviates the limitations of isolated perfused liver preparations associated with alterations in the metabolic state of the liver.

6208 THE HEPATIC CLEARANCE OF CIRCULATING NATIVE AND ASIALO CARCINOEMBRYONIC ANTIGEN BY THE RAT. (Eng.) Thomas, P.; Hems, D. A. (Chester Beatty Res. Inst., Royal Cancer Hosp., Fulham Road, London, SW3 6JB, U.K.). *Biochem. Biophys. Res. Commun.* 67(3):1205-1209; 1975.

The fate of circulating native and asialo-carcinoembryonic antigens (CEA), in concentrations larger than those in previous studies, were studied in intact Sprague-Dawley rats and in perfused rat livers. The changes in immunologically active glycoprotein were followed with a radioimmunoassay (rather than with iodine-labeled material, as in previous studies). Female rats received CEA (90 μg) i.v. The intact rat accumulated 76% of CEA in the liver, 2% in the spleen, and 3% in the lung. The half-life of the native glycoprotein in the liver perfusion system was 28 min, while that of the asialo-glycoprotein was 11 min. In both cases, the time course for removal of glycoprotein from the perfusate was first order. After 90 min of perfusion, about 10% of the glycoprotein was found in the bile. The rapid uptake of the native glycoprotein suggests that the recognition of terminal galactose may not be the only factor involved in determining the hepatic assimilation of glycoproteins.

6209 ENZYMATIC ANALYSIS OF BILE ACIDS. (Eng.) Macdonald, I. A. (Dept. Medicine, Dalhousie Univ., Halifax, Nova Scotia, B3H 4H7 Canada). *Clin. Biochem.* 9(3):153-154; 1976.

The use of enzymes and thin-layer chromatography (TLC) in quantifying individual bile acids from bile or serum is reviewed. Both 3α-hydroxysteroid dehydrogenase (3α-HSDH) from *P. testosteroni* and 7α-hydroxysteroid dehydrogenase from *Escherichia coli* can be used for spectrophotometric or fluorometric measurement of individual bile acids in TLC eluates. Pool size and half-life of serially labeled samples can be estimated using these enzymes, provided enzymatically measurable minor bile acid components and enzymatically nonmeasurable compounds (such as ketobile acids and bile-acid sulphates) are present in negligible amounts. As many as 200 individual bile samples have been analyzed in this way, and the method has been extended to serum. Technical difficulties, such as interference in the 3α-HSDH assay by free fatty acids, ethanol, and other higher alcohols, and loss of linearity at the upper end of the calibration curve, can be physically avoided. The use of ethanol and higher alcohols is avoided with the 7α-HSDH assay also.

6210 BILE ACID POOL IN WISTAR RATS. (Eng.) Fisher, M. M.; Kakis, G.; Yousef, I. M. (Dept. Medicine and Pathology, Univ. Toronto, Toronto, Ontario, Canada M5S 1AB). *Lipids* 11(2):93-96; 1976.

The size of the bile acid pool in male and female

200-g Wistar rats was studied. Six male and six female rats received standard laboratory chow during the 3-week study period, and similar numbers of rats received a powdered semisynthetic diet. The total bile acid pool was approximately 100 µmol in animals on the chow diet and 60 µmol in those on the semisynthetic diet. Regardless of sex or diet, 97% of the bile acid pool was located in the intestinal tract. There was no sex difference in the size of the bile acid pool nor in the concentration of bile acids in the intestinal tract or blood. However, the females fed the chow diet had a significantly higher hepatic bile acid concentration (0.33 µmol/g liver) than did the males (0.19 µmol/g). Cholic acid comprised 55-73% of the bile acid pool. In the intestinal tract of the female rats, the molar percent distribution of cholic acid (71.3 in those on chow, 63.3 in those on semisynthetic diet), lithocholic acid (1.6 and 2.0, resp.), and, in those receiving the semisynthetic diet, chenodeoxycholic acid (14.6) was higher than in males (cholic, 54.8 in those on chow, 55.4 in those on semisynthetic diet; lithocholic, 0.8 and 0.8, resp.; chenodeoxycholic, 11.1). The relative concentrations of deoxycholic acid, β-muricholic acid, and hyodeoxycholic acid were significantly higher in males. The estimated bile acid pool size in these experiments is at least twice that of published estimates. The observation that both the concentration and relative composition of the bile acids in the blood plasma reflected changes in the bile acid content of the intestinal tract suggests that analysis of plasma bile acids might prove useful in future studies on the bile acid pool in general.

6211 A PROBABLE ESSENTIAL DERIVATIVE OF LINOLEIC ACID: LIPOIC ACID, UNIVERSAL COENZYME OF THE OXIDATION OF ALPHA-KETONE ACIDS.

(Fre.) Carreau, J.-P.; Lapous, D.; Raulin, J. (Hopital de Bicetre, 94270 Le Kremlin-Bicetre, France). *C. R. Acad. Sci. [D] (Paris)* 281(13):941-944; 1975.

To determine the metabolite(s) of the "essential" fatty acids responsible for the "essential" character, ^{14}C-labeled linoleic acid (LI) or oleic acid (OL, 1 µCi) was injected in 6-day-old rats born of mothers fed a lipid deficient diet during the last two-thirds of pregnancy. Rats were sacrificed 3 hr later and their livers were homogenized in a chloroform-methanol-water mixture. After decantation of the liposoluble phase, the alcohol-water and macromolecule phases were subjected to electrophoresis, gas-liquid chromatography, and mass spectrophotometry. On analysis, the substance covalently bound to the proteins, and could only be separated by hydrolysis with 6 N HCL, suggesting a lipoic acid, the universal coenzyme of the multienzyme complex of oxidative decarboxylations. The significance of lipoic acid in the metabolic chain, which appears to originate from linoleic acid, has not been determined.

6212 METABOLISM OF SHORT CHAIN FATTY ACID IN RAT LIVER IN BILIARY OBSTRUCTION.

(Eng.) Koyama, K.; Kashimura, S.; Yamauchi, H.; Takagi, Y.; Owada, Y.; Sato, T. (Tohoku Univ. Sch. Medicine, Sendai, Japan). *Tohoku J. Exp. Med.* 117(4):335-341; 1975.

In an attempt to clarify the hepatic insufficiency in obstructive jaundice, the hepatic metabolic rate of n-butyric acid, ketogenesis, and CO_2 formation from butyric acid were investigated using liver slices obtained from Wistar rats subjected to choledochal ligation or injected i.p. with 20% carbon tetrachloride (1 ml/100 g). The hepatic metabolic rate of n-butyric acid was reduced with the prolongation of biliary obstruction. The reduction was presumed to be caused for the most part by the reduced ketogenesis (which also decreased with the duration of biliary obstruction), and in part, by the impairment of the citric acid cycle (TCA-cycle). Three to four weeks after biliary obstruction, the metabolic rate was reduced to a level comparable to liver necrosis produced by CCl_4. It is postulated that this reduction is one of the pathogenic factors in fatal liver insufficiency in many cases of obstructive jaundice. Although the reduction is mild and mobile in the early stage of jaundice, the obstruction should be relieved as early as possible.

6213 VALUE OF LYSOSOMAL ENZYMES IN CANINE LIVER PRESERVATION.

(Eng.) Smeesters, C.; Bloch, P.; Fourtanier, G.; Corman, J. L.; Daloze, P. M. (Hopital Notre-Dame, Montreal, Canada). *Surg. Forum* 26:431-433; 1975.

Because of the importance of the release of lysosomal enzymes in liver ischemia, potential liver viability was correlated with the activity of lysosomal β-galactosidase (BGa) released during and after two modes of liver preservation in dogs. Seventeen controls underwent either liver autotransplant or orthotopic transplant of homologous livers, revascularized immediately after their perfusion or excision. In the first experimental group, six livers were homotransplanted after a 24-hr continuous semipulsatile perfusion with an albumineous extracellular perfusate at 15 C. In experimental group 2, 10 livers were homotransplanted after infusion with hyperosmolar intracellular type of ice-cold preservation fluid in which they were subsequently stored for 24 hr at 4 C. In group 1, perfusate BGa activities increased exponentially until the end of perfusion. In group 2, only negligible activity was detected at any time in the infusates. In both groups, maximal BGa activity was usually measured in the recipients' serum within 2-3 hr after revascularization of the preserved organs. The mean maximum BGa value in the four animals in group 1 that survived more than 48 hr was 4,116 mU/g protein/100 ml sample; in the unsuccessful transplants, the mean value was 8,954 mU/g/100 ml. The maximum BGa value in six surviving animals in group 2 was 2,744 mU/g/100 ml, and for the nonsurviving animals, it was 10,099 mU/g/100 ml. In all surviving animals, these values returned to near normal levels from the first postoperative day on and remained at normal values on subsequent days. Lysosomal BGa activity appears to be a sensitive index of the degree of liver damage sustained during preservation. BGa activity also appears to be valuable in the perfusion procedures in predicting liver viability before transplantation.

6214 DIETARY FATS AND PROPERTIES OF ENDOPLASMIC RETICULUM: II. DIETARY LIPID INDUCED CHANGES IN ACTIVITIES OF DRUG METABOLIZING ENZYMES IN LIVER AND DUODENUM OF RAT.

(Eng.) Hietanen, E.; Laitinen, M.; Vainio, H.; Hanninen, O. (Dept. Physiology, Univ. Kuopio, SF-70100 Kuopio, Finland). *Lipids* 10(8):467-472; 1975.

Thirty male Wistar rats were fed cholesterol, cacao butter, olive oil, or standard control diets for 4 weeks to determine the effect of dietary lipids on the rate of drug biotransformation in the liver and duodenum. The cholesterol-rich diet maintained the hepatic aryl hydrocarbon hydroxylase activity at the same level as did the standard diet. Rats fed olive oil and cacao butter diets showed lower hepatic aryl hydrocarbon hydroxylase activity (10-15% of the standard diet). The *p*-nitroanisole *O*-demethylase activity was doubled in the hepatic microsomes of rats fed the high cholesterol diet, compared with rats fed the standard diet. The hepatic uridine diphosphate glucuronosyltransferase activity showed different patterns, depending on the *in vitro* treatment of the microsomal membranes. If the enzyme activity was assayed from the native, untreated microsomes, an increase in the measurable uridine diphosphate glucuronosyl transferase activity was found in rats on the cholesterol-rich diet. After the *in vitro* activation of membrane-bound uridine diphosphate glucuronosyltransferase by trypsin, the increase in measurable activity was 10-fold in the group fed the standard diet, 6-fold in group fed cholesterol, 4-fold in group fed cacao butter, and 3-fold in group fed olive oil. Trypsin digestion of microsomes increased the measurable uridine diphosphate glucuronosyltransferase activity less in rats fed diets rich in neutral fats than those fed the standard diet. In the duodenal mucosa, the aryl hydrocarbon hydroxylase activity in the rats fed the lipid diets was 30-50% of that in the rats fed the standard diet. The intestinal uridine diphosphate glucuronosyltransferase activity was highest in the standard diet and cholesterol groups. The rats fed neutral fat diets showed 50-80% of the activity found in the group fed the standard diet. It is concluded that excessive dietary lipids may interfere with the hepatic and intestinal capacity to detoxify drugs.

6215 INDIVIDUAL DIFFERENCES IN THE OCCURRENCE OF A LIPID PEROXIDATION INHIBITOR IN RAT LIVER SOLUBLE FRACTION.

(Eng.) Kamataki, T.· Aikawa, K.; Ozawa, N.; Kitagawa, H. (Dept. Biochemical Pharmacology, Faculty Pharmaceutical Sciences, Univ. Chiba, Yayoi-cho, Chiba 280, Japan). *Jpn. J. Pharmacol.* 25(6):793-796; 1975.

Individual differences in the occurrence of lipid peroxidation inhibitor in the cytosol of rat liver were studied, and the effect of these differences on the activity of ethylmorphine N-demethylase was examined. Preincubation of the 9.000 x *g* supernatant of male Wistar rat liver with an NADPH-generating system resulted in lipid peroxidation. Among the livers of five rats, the amount of lipid peroxidation was small (0.72-2.04 nmol malondialdehyde formed/mg microsomal protein/30 min) in three and markedly higher (13.74-15.13 nmol/mg/30 min) in the other two. When 33 μM EDTA was added to the preincubation medium, lipid peroxidation was almost completely inhibited, and no difference in the levels of lipid peroxidation was seen between the various rats. The effects of the preincubation of the 9,000 x *g* supernatants with an NADPH-generating system in the presence and absence of EDTA on ethylmorphine N-demethylase activity were studied. In the three rat livers with small amounts of lipid peroxidation, there was little difference in the activity of ethylmorphine N-demethylase in incubations carried out in the presence of EDTA (40-56 nmol formaldehyde formed/mg microsomal protein/15 min) or in the absence of EDTA (51-65 nmol/mg/15 min). In contrast, large differences in the activity toward ethylmorphine were seen when the supernatants from the two remaining rats were incubated with substrate in the absence of EDTA (19 and 10 nmol/mg/15 min) compared with the presence of EDTA (53 and 46 nmol/mg/15 min, resp.). The low amounts of lipid peroxidation in the first three rats are probably due to the inhibition of lipid peroxidation by factor(s) in the cytosol. The results suggest that factor(s) in the cytosol stabilize ethylmorphine N-demethylase activity by inhibiting lipid peroxidation.

6216 DYNAMICS OF LIVER GLYCOGEN: THE TOPOCHEMISTRY OF GLYCOGEN SYNTHESIS, GLYCOGEN CONTENT AND GLYCOGENOLYSIS UNDER THE EXPERIMENTAL CONDITIONS OF GLYCOGEN ACCUMULATION AND DEPLETION.

(Eng.) Sasse, D. (Lehrstuhl Anatomie III, Universitat Freiburg/Br., D-7800 Freiburg/Br., Albertstrasse 17, W. Germany). *Histochemistry* 45(3):237-254; 1975.

Using histochemical techniques, the glycogen content and the activities of glycogen synthetase (UDPGGT) and phosphorylase were studied in the livers of 106 golden hamsters under the following experimental conditions: starvation of 16, 36, 48, 72, and 96 hr; alloxan-diabetes of 24, 48, and 72 hr; and insulin-treatment (2 U, i.p.) after 24, 48, and 72 hr of alloxan-diabetes. Starvation led to a depletion of liver glycogen during the first 48 hr, which was finally restricted to zone 3 of the liver acinus. After starvation of 72 and 96 hr, a new glycogen accumulation was seen in the microvasculatory periphery of the acinus (zone 3 and 2). The process of glycogen depletion was characterized in the beginning by a high phosphorylase activity in all zones of the acinus, later only in the forefield of glycogen content. The weak activity of glycogen synthetase was mainly restricted to zone 3. All phases of glycogen depletion were found in alloxan-diabetic animals. Of 45 hamsters, 23 showed an extreme depletion of glycogen; typical for this situation was a weak or absent glycogen synthetase activity in zone 3 and a broad field of phosphorylase activity in zones 1 and 2. The short stimulation by insulin caused a considerable increase in glycogen synthetase activity at the portally oriented border of the glycogen area, and a shift of the moderate phosphorylase activity of zone 1 also occurred. The results indicate that a shift of the reduced glycogen content in the direction of the microvasculatory periphery of the liver acinus (zone 3) is caused by high phosphorylase activity in the portal forefield, and that glycogen synthetase activity is low in the glycogen area. After a short phase of glycogen synthesis in all hepatocytes, a moderate phosphorylase activity in zone 1 leads to a mobilization of the portal glycogen deposits and to an increasing accumulation of glycogen in the peripheral part of the acinus. At the portally oriented border of the glycogen area, a high synthetase activity leads to a broadening of the glycogen area in the direction of the portal branches. At the end of this process, the "normal" pattern of the liver acinus occurs. All hepatocytes are filled with glycogen; and the glycogen enzymes are restricted to the periportal border of zone 1.

6217 HETEROGENEITY OF HEPATIC VITAMIN B_{12} IN THE RAT AFTER PARENTERAL CYANOCOBALAMIN.

(Eng.) Cooksley, W. G. E.; Tavill, A. S. (MRC Clinical Res. Center, Harrow, Middlesex, England). *Clin. Sci. Mol. Med.* 49(3):257-264; 1975.

The rate of radioactive vitamin B_{12} excretion into plasma and bile from the isolated perfused Sprague-Dawley rat liver and into bile *in vivo* was measured after the i.m. injection of radioactive cyanocobalamin (15 pmol ^{57}Co-labeled cyanocobalamin or 240 pmol ^{58}Co-labelled cyanocobalamin) at short time intervals. The results were compared with those studies carried out after a longer time interval. After the shorter period of prelabeling (<7 days), there was a biphasic release of radioactive vitamin B_{12} by the isolated perfused liver over 4 hr: an initial rapid rate followed by a slower rate after about 1 hr of perfusion. The rates of total radioactive vitamin B_{12} excretion were 25% and 5% of the hepatic radioactivity into plasma and bile, resp., during the 4-hr perfusion of a liver labeled 18 hr previously. In contrast, the previous results showed that the long labeling period ($\geq$ 10 days) was associated with a linear release of radioactive vitamin B_{12}, and the total release into plasma and bile was decreased in comparison to the short labeling period (13.5% and 1% for plasma and bile, resp.). Confirmation of coexisting stable and labile pools of intrahepatic vitamin B_{12} was provided by: the patterns of hepatic release after double labeling with ^{57}Co-labeled and ^{58}Co-labeled cyanocobalamin at different times before liver perfusion and the rates of biliary excretion of ^{57}Co-labeled and ^{58}Co-labeled vitamin B_{12} *in vivo* after different periods of prelabeling. The rate and pattern of release were not altered by changes in the quantity of precursor cyanocobalamin (0.44, 1.1, and 44 nmol), by phenobarbitone (0.4 mmol/kg daily for 5 days) treatment, or by the addition of cycloheximide (10-18 μM) to the perfusion. The i.m. injection into rats of subcellular preparations of rat liver labeled *in vivo* with radioactive vitamin B_{12} demonstrated that hepatic heterogeneity did not depend on physical compartmentalization. Despite the rapid release from the liver of recently administered radioactive cyanocobalamin, the hepatic radioactivity increased progressively with time after labeling *in vivo*, in contrast to the other tissues, in which it decreased. In the presence of rapid bidirectional fluxes, the ability of the liver to store vitamin B_{12} can be largely explained by the reduction in the rate of hepatic release that continues for about 10 days after parenteral administration of cyanocobalamin.

6218 HEPATIC REGENERATION AND LYMPHOCYTE ACTIVITY.

(Eng.) Sakai, A.; Pfeffermann, R.; Mashimo, S.; Goldson, H.; Kountz, S. L. (Downstate Medical Center, Brooklyn, NY). *Surg. Forum* 26:406-408; 1975.

Two experiments were carried out to support the theory that lymphocyte activity is closely related to the liver function. The mean level of DNA synthesis in normal Lewis rat hepatocytes and lymphocytes, cultured with serum from rats that had undergone 70% hepatectomy, was significantly greater (12,740 counts per min in hepatocytes; 1,844 counts per min in lymphocytes) than that in hepatocytes and lymphocytes cultured in the sera of sham-operated rats (5,240 and 1,644 counts per min, resp.) or in normal sera (6,380 and 1,844 counts per min, resp.). In the second experiment, lethally irradiated (650 rads) Lewis rats were subjected to a 70% hepatectomy. The effect of the transfer of lymphocytes (1.5×10^8 cells, i.v.) taken from the spleens of normal rats or those with partial hepatectomy on the recovery of regeneration capacity was studied by counting the number of liver cells 10 days later. After partial hepatectomy alone, the mean number of liver cells was 20.79×10^6. In rats irradiated following partial hepatectomy, this number was only 8.20×10^6 cells. Total recovery of the regenerative capacity was achieved by the transfer of lymphocytes from the partially hepatectomized rats, the number of cells being 20.86×10^6. The number of cells after the transfer of normal lymphocytes was 14.64×10^6. The results suggest that partial hepatectomy increases the mitogenic serum factor, but does not decrease an inhibitor, and that a common pathway of the nucleic acid synthesis may be present in the regenerative hepatocytes and lymphocytes. These results, together with the fact that liver cells can be used in place of bone marrow cells to reconstitute lethally irradiated animals, indicate that there is a mutual pathway between the lymphocytes and liver cells.

6219 ROLE OF CHANGES IN PROTEIN DEGRADATION IN THE GROWTH OF REGENERATING LIVERS.

(Eng.) Scornik, O. A.; Bothol, V. (Dartmouth Medical Sch., Hanover, NH 03755). *J. Biol. Chem.* 251(10):2891-2897; 1976.

The significance of changes in rates of synthesis, export, and degradation of proteins during liver regeneration was assessed in male CD-1 mice. Proteins were pulse-labeled by the i.v. injection of radioactive leucine, and, 5 min later, by the injection of 0.4 mg pactamycin. One-half of the protein radioactivity was lost from the normal liver within 3 hr. From the radioactivity of the plasma proteins at that time and a study of the disappearance of these proteins from the circulation, it was calculated that 28% of the newly synthesized proteins were exported. Serum albumin accounted for a third of the exported proteins. Thirty-six hours after partial hepatectomy, the proportion of albumin to total protein synthesis remained constant, while that of the other plasma proteins increased by 50%. The fraction of the newly synthesized proteins retained by the liver after 3 hr decreased by 20%. During the first 36 hr of liver regeneration, the average rates of protein degradation slowed down to one-half the normal values. This was determined either by the loss of radioactivity from total protein (the guanidino-C of protein-bound arginine) in livers labeled with [^{14}C]bicarbonate, or calculated as the balance between protein synthesis and net protein gain. From these results, and those of a previous study of the protein synthetic machinery of normal and regenerating livers, it is concluded that changes in the rate of protein degradation are the single most important factor determining the increase in protein content during liver compensatory growth.

6220 THE CONTROL OF LIVER REGENERATION BY PARATHYROID HORMONE AND CALCIUM. (Eng.) Rixon, R. H.; Whitfield, J. F. (Natl. Res. Council Canada, Ottawa, Canada K1A 0R6). *J. Cell. Physiol.* 87(2):147-155; 1976.

The mechanism involved in proliferative incompetence, occurring when the liver is exposed to hypocalcemic conditions prior to partial hepatectomy, was studied in male, pathogen-free, Sprague-Dawley rats. Following 68% hepatectomy, there were two bursts of hepatocyte DNA-synthetic and mitotic activity that were produced by two subpopulations having different rates of (nearly synchronous) proliferative development. Only about 50% of the cells in both subpopulations could initiate DNA synthesis and enter mitosis when exposed to the hypocalcemic conditions in the parathyroprivic rat for 24 hr before partial hepatectomy. The proliferatively incompetent hepatocytes in these hypocalcemic rats were induced to initiate their DNA synthetic and mitotic activity by an i.p. injection of the calcium-mobilizing parathyroid hormone (50 USP U/100 g) as late as 12 hr after partial hepatectomy. Single i.p. injections of calcium (0.25 mg/100 g) also restored the proliferative competence of these hepatocytes, but only when injected at specific periods following partial hepatectomy. The injection of calcium, 12-15 hr after partial hepatectomy, induced hepatocytes in the first subpopulation to finish their development and enter mitosis, but did not affect the second, more slowly developing, subpopulation. Calcium had to be injected 25 hr after partial hepatectomy to stimulate proliferation in this second subpopulation. These data suggest that the hepatocytes that became proliferatively incompetent by prolonged exposure to a hypocalcemic environment are proliferatively activated by partial hepatectomy, but that their proliferative development stops at a calcium-dependent stage near the end of the prereplicative phase of development.

6221 DEGRADATION OF HEPATIC HAEM TO PORPHYRINS AND OXOPHLORINS IN RATS TREATED WITH 2-ALLYL-2-ISOPROPYLACETAMIDE. (Eng.) McDonagh, A. F.; Pospisil, R.; Meyer, U. A. (Dept. Medicine, Univ. California, San Francisco, CA 94143). *Biochem. Soc. Trans.* 4(2):297-298; 1976.

The destruction of the microsomal hemoprotein, cytochrome P-450, and loss of microsomal heme, which is accompanied by the formation of green-brown pigments known to be iron-free metabolites of the heme group of cytochrome P-450, was studied in Sprague-Dawley rats. Sodium phenobarbital (75 mg/kg, s.c.) was administered for 4 consecutive days before the administration of 2-allyl-2-isopropylacetamide (400 mg/kg). Chromatography revealed two major greenish-brown bands that fluoresced red (pigments 1 and 2). Four green bands (pigments 3-6) with a weak red fluorescence were also detected. Pigments 1 and 2 were identified as porphyrins by their absorption spectra. Pigments 3-6 were unstable and were recognized as oxophlorins by the changes in their acid titration spectra. Similarities in the spectra of porphyrins 1 and 2 and oxophlorins 3-6 indicated that these compounds may comprise two groups of isomers (1 and 2 isomeric, 3-6 isomeric). The spectra also indicated that all six pigments are substituted, probably in the 2 and 4 positions, with electron-withdrawing groups. The presence of oxophlorins among the "green pigments" suggests that free radicals may play a role in their formation. These studies show that the porphyrin ring is not opened when hepatic heme is degraded to "green pigments" in rats treated with 2-allyl-2-isopropylacetamide.

6222 PHOSPHOLIPID METABOLISM OF THE WHOLE LIVER, MITOCHONDRIA AND MICROSOMES DISTURBED BY ACUTE THIOACETAMIDE INTOXICATION, AND THE ACTION OF SILYMARIN. (Ger.) Schriewer, H.; Lohmann, J. (Physiologisch-Chemisches Institut, Westfalische Wilhelms-Universitat, 44 Munster/Westf., Waldeyerstr. 15, W. Germany). *Arzneim. Forsch.* 26(1):65-69; 1976.

The effect of thioacetamide (TAM) on lipid content and palmitate incorporation in hepatocyte organelle phospholipids and in whole liver and the effect of silymar (SYM) on hepatoprophylaxis are examined. Male Wistar rats received SYM (400 mg, i.p.) 60 min before the administration of TAM (300 mg/kg, i.p.). Labeled palmitate (PAL, 11.3 µCi/animal) was injected i.v. 20 minutes before sacrifice. TAM induced a statistically insignificant depression in the radioactivity of total lipids, total phospholipids, and phosphatidylcholine (PPC) and an increase in phosphatidylethanolamine (PEA). After SYM administration, the control levels were approximated. In liver homogenates, total lipid, triglyceride, and phospholipid increased. The reduction in specific mitochondrial PEA radioactivity by TAM was abolished by SYM, which was also prophylactic of TAM-induced changes in mitochondrial phospholipid concentrations. Microsomal phospholipid radioactivity was diminished by TAM, but only significantly for PEA; SYM is not prophylactic. SYM normalizes TAM-induced changes in microsomal phospholipid concentrations; PPC is elevated, and PEA diminished.

6223 EFFECT OF LYSINE ACETYLSALICYLATE ON BILIARY LIPID SECRETION IN DOGS.

(Eng.) Erlinger, S.; Bienfait, D.; Poupon, R.; Dumont, M.; Duval, M. (Hopital Beaujon, 92110 Clichy, France). *Clin. Sci. Mol. Med.* 49(3):253-256; 1975.

Because of the need for nonhepatotoxic drugs that reduce the cholesterol saturation of bile, the influence of i.v.-administered lysine acetylsalicylate on biliary lipid secretion was studied in four unanesthetized dogs with Thomas duodenal cannulae. Lysine acetylsalicylate (8.3 mmol, followed by a constant infusion of 0.2 mmol/min) increased bile flow from a mean control level of 0.14 ml/min to 0.45 ml/min, and erythritol clearance increased in parallel, from a mean control level of 0.24 ml/min to 0.63 ml/min. The bile salt secretion remained unchanged, suggesting that the compound stimulated the formation of the canalicular (hepatocytic) bile salt-independent fraction of bile flow. Lysine acetylsalicylate induced significant decreases in biliary phospholipid secretion from a mean control level of 2.9 µmol/min to 0.9 µmol/min and cholesterol secretion from a mean control level of 136 nmol/min to 5.9 nmol/min. The cholesterol saturation of bile was significantly reduced from a control level of 1.1 µmol/ml to 0.1 µmol/ml ($p<0.005$). It is postulated that the decrease in phospholipid and cholesterol secretion resulted from the dilution of intracanalicular bile salts. This effect of lysine acetylsalicylate, and possibly of other bile salt-independent choleretics, may be of value in the treatment of cholesterol gallstones in man.

6224 DIRECT EFFECTS OF VARIOUS CATECHOLAMINES ON LIVER CIRCULATION IN DOGS.

(Eng.) Hirsch, L. J.; Ayabe, T.; Glick, G. (Michael Reese Hosp., Chicago, IL 60616). *Am. J. Physiol.* 230(5):1394-1399; 1976.

Experiments were carried out in 25 dogs to elucidate the response of the splanchnic bed to various catecholamines, and attempts were made to define the roles of various receptors in these responses. As measured by electromagnetic blood flow transducers, the direct infusion of epinephrine (0.1 µg/kg/min), norepinephrine (0.1 µg/kg/min), and dopamine (2.0 µg/kg/min) into the portal vein (PV) produced a 40-50% decrease in hepatic arterial (HA) blood flow; isoproterenol (0.1 µg/kg/min) increased HA flow by about 69%. No changes in PV flow or pressure were observed. Direct HA infusion of the vasoconstrictors decreased HA flow by amounts comparable to those occurring after PV infusion. HA infusion of isoproterenol increased HA flow only 15% suggesting a difference in beta-receptor population in the two vessels. When infused directly into the superior mesenteric artery (SMA), epinephrine and norepinephrine reduced SMA flow by about 45% and PV flow by 20-25%; HA flow increased 6-8%. Infusion of isoproterenol and dopamine into SMA increased SMA flow by 115% and 206%, resp., and PV flow by 60% and 70%, resp. HA flow was decreased by 25% and 50%, resp. Portal vein pressure increased less than 3 mm Hg. Alpha- and beta-receptor blockade of the liver did not significantly change the alterations in hepatic arterial blood flow that were secondary to changes in portal venous blood flow. It is likely that regulation of hepatic arterial flow resides in mechanisms located within the liver sinusoids.

6225 CHLORAMPHENICOL-INDUCED GIANT HEPATIC MITOCHONDRIA.

(Eng.) Albring, M.; Radsak, K.; Thoenes, W. (Institut fur Cytobiologie und Cytopathologie, Universitat Marburg/Lahn, Marburg, W. Germany). *Naturwissenschaften* 62(1):43-44; 1975.

Since chloramphenicol has a selective inhibitory action on mitochondrial translation and has negligible effects on cytoplasmic synthetic processes, it was used in an investigation of the mechanism of development of giant hepatic mitochondria. Weanling mice were maintained on a diet containing 1.5% chloramphenicol-stearylglycolate for 10-13 days. All hepatocytes contained grossly enlarged mitochondria measuring 2-10 µm. Some of the organelles exhibited a striking reduction or complete loss of the inner membrane infoldings, whereas in others, cristae arranged in circular, looplike, or whorled patterns were observed. Megamitochondria were not thought to be produced by osmotic swelling, since the density of the matrix remained constant in organelles of different size within a given tissue section and was comparable to the density of control mitochondria in sections of essentially identical thickness. The results confirm the hypothesis that one mechanism for the development of giant mitochondria may be impairment of mitochondrial translation.

6226 THE ROLE OF MICROSOMAL HYDROXYLASES IN THE MODIFICATION OF CHLOROFORM HEPATOTOXICITY IN RATS.

(Eng.) Gopinath, C.; Ford, E. J. H. (Drug Safety Lab., Organon International, B.V. Oss, Netherlands). *Br. J. Exp. Pathol.* 56(5):412-422; 1975.

The relative activities of agents that alter the drug metabolism enzyme systems in the rat liver were compared using the following parameters: effects on hexobarbitone sleeping time (HST), effects on hepatic amidopyrine N-demethylase (MAD) activity, and the ability to modify chloroform toxicity. Male Wistar rats were used as they had greater mean MAD activity [6.0 g aminoantipyrine (AAP)/g/30 min] per unit weight liver, shorter HST (22.7 min), and were more susceptible to chloroform hepatotoxicity than females. Rats received one of the following treatments prior to the chloroform administration: phenobarbitone sodium (1 g/l in drinking water, 7 or 14 days), phenylbutazone (i.p., 5 days), chloropromazine (10 mg/kg/day x 7, i.p.), SKF 525A (50 mg/kg, i.p.), sodium diethyl dithiocarbamate (50 mg/kg, i.p.), carbon disulfide (0.5 ml/kg, p.o.), or *o,p*-chlorophenothane (DDT, 10 mg/kg, p.o.). All but the last group received chloroform at 0.75 ml/kg; those treated with phenobarbitone received 0.5 ml/kg. The livers of rats treated with phenobarbitone became pale and enlarged. There were large areas of coagulative necrosis, the smooth endoplasmic reticulum was severely swollen, and other organelles showed swelling or other signs of damage. The rats treated for 7 days had 47.9% necrotic and 6.9% degenerate cells; in comparison, the mean percentages in male control rats treated only with chloroform were 5.7% and 38.9%, resp. The mean HST and MAD were 12.5 min and 22.7 g AAP/g/30 min, resp., whereas these levels in chloroform-treated controls were 22.7 min and 6.0 g AAP/g/30 min, resp. In rats treated for 14 days, the values were 7.7 min and 52.1 g AAP/g/30 min, resp. Rats treated with phenylbutazone and chloroform had enlarged pale livers with accentuated lobulation. Centrilobular necrosis was present. The percentages of necrotic and degenerative cells were 30.4% and 7.5%, resp. HST and MAD were 10.0 min and 16.2 g AAP/g/30 min, resp. Of the six rats given chlorpromazine and chloroform, three had large necrotic areas around the central veins, surrounded by areas of degenerating cells. The percentages of necrotic and degenerate cells were 15.1% and 11.4%, resp. HST and MAD were 17.0 min and 5.4 g AAP/g/30 min. Rats that received sodium diethyl dithiocarbamate and chloroform showed no necrosis. HST was 36.2 min. In the rats given SKF 525A and chloroform, the percentages of necrotic and degenerating cells were 2.0% and 7.8%, resp. HST was 323.2 min. The rats receiving carbon disulfide showed no necrosis, but there was isolated cell degeneration (0.1%). The rats given DDT had HST and MAD values of 15.6 min and 34.5 g AAP/g/30 min. It is concluded that HST, MAD, and chloroform susceptibility are altered markedly by pretreatment with agents that alter the drug metabolizing enzyme system.

6227 INFLUENCE OF DOPAMINE ON THE PRESSURE IN THE HEPATIC VEIN.

(Ger.) Benko, H.; Peschl, L.; Schuller, J.; Neumayr, A. (Kaiserin-Elisabeth-Spital, Huglgasse 1, A-1150 Vienna, Austria). *Acta Med. Austriaca* 2(5):187-190; 1975.

Dopamine-induced changes in hepatic vein occlusion pressure were studied in 12 cirrhotic patients. The clinical sample included six men and six women, 35-70 yr of age; eight had ethanol cirrhosis, and four were postnecrotic. The patients received 3, 4, and 6 gamma/kg/min dopamine infusions; catheterization was via a cubital vein. Hepatic vein pressure was significantly ($p<0.005$) increased by 3 gamma; 4 and 6 gamma continued the elevation to 22% and 29%, resp., ($r=0.996$). There was no significant relation between initial hepatic vein pressure and dopamine elevation at any dose. The dopamine-induced effect is very short. The systolic pressure increased 2.5 mm Hg under 3 gamma. The mean arterial pressure rose 2, 8.5, and 14.5 mm Hg, resp., after 3, 4, and 6 gamma. The difference between the dopamine-induced effect at 6 and 3 gamma, and at 6 gamma and control levels, is significant ($p<0.005$). There was no significant correlation between changes in hepatic vein and arterial blood pressure. A dose of 3 gamma also elicited a significant increase in renal plasma flow and glomerular filtrate in cirrhosis. The 3 gamma dose is recommended for low-risk renal perfusion in cases of cirrhotic portal hypertension.

6228 ACETALDEHYDE LEVELS DURING ETHANOL OXIDATION: A DIET-INDUCED CHANGE AND ITS RELATION TO LIVER ALDEHYDE DEHYDROGENASE AND REDOX STATES.

(Eng.) Lindros, K. O.; Koivula, T.; Eriksson, C. J. P. (Res. Lab. State Alcohol Monopoly (Alko), Box 350, SF-00101 Helsinki 10, Finland). *Life Sci.* 17(10):1589-1597; 1975.

The effects of diet on ethanol elimination, blood acetaldehyde, and voluntary alcohol intake were investigated in female AA rats. The rats were given one of three diets for 2 weeks: A containing 34% protein and 3.6% fat, B containing 34% protein and 8% fat, and C containing 20% protein for 2 weeks. Each animal was given 1.5 g ethanol/kg body weight, i.p., and blood samples were taken and analyzed for ethanol and acetaldehyde. The animals were maintained on the diets for a further 7 weeks and were given free choice of 10% ethanol. Blood samples were taken again before and after administration of 1.5 g ethanol. Blood acetaldehyde levels were several times higher in rats maintained on diet A, even after only 2 weeks than in those maintained on diets B and C. The levels persisted 6 weeks later, when the rate of ethanol elimination was significantly faster in both the B ($p<0.01$) and C groups ($p<0.001$). Significant differences were found in levels of acetoacetate and acetaldehyde, both of which were significantly higher in the livers of diet A rats than in those on diet B ($p<0.001$ for acetoacetate and $p<0.001$ for acetaldehyde) or diet C ($p<0.01$ for acetoacetate and $p<0.05$ for acetaldehyde). The ethanol/acetaldehyde ratio in the liver was significantly lower in the rats on diet A than in the rats on diet B ($p<0.01$). The aldehyde dehydrogenase activity was significantly lower in the livers from rats fed on the A diet. The activity of the low-K_m enzyme with 0.12 mM acetaldehyde as substrate was about twice as high in livers from groups B and C. The results demonstrate that an unknown dietary factor causing a decreased activity of aldehyde dehydrogenase, especially of the low-K_m type, induces high liver and blood acetaldehyde concentrations during ethanol oxidation.

6229 CYCLIC AMP-LINKED MECHANISMS IN ETHANOL-INDUCED DERANGEMENTS OF METABOLISM IN RAT LIVER AND ADIPOSE TISSUE.

(Eng.) Jauhonen, V.

P.; Savolainen, M. J.; Hassinen, I. E. (Dept. Medical Biochemistry, Univ. Oulu, SF-90220 Oulu 22, Finland). *Biochem. Pharmacol.* 24(20):1879-1883; 1975.

To study the effects of ethanol on cyclic AMP (cAMP)-linked mechanisms *in vivo*, an acute ethanol load was induced by gastric administration of ethanol (5 g/kg) to fasted male Long-Evans rats. The concentrations of cAMP during the following 24 hr, measured in the liver and adipose tissue, were correlated with simultaneously measured concentrations of blood glucose, plasma free fatty acids (FFA), hepatic triglycerides (TG), hepatic glycogen, and blood ethanol. Ethanol induced a significant increase in hepatic cAMP, reaching a maximum at 16 hr after administration. Hepatic glycogen decreased 15-fold after 6 hr, and blood glucose decreased slightly. Plasma FFA levels decreased significantly, with a minimum at 4 hr. Hepatic TG levels increased steadily from 6 to 24 hr after the ethanol administration, reaching about a fivefold increase at 24 hr. An unexpected small decrease in adipose tissue cAMP was observed. In neither hepatic nor adipose tissue did the cAMP concentration correlate with the blood ethanol concentration. It is concluded that the changes in cAMP are more likely to be due to the regulation of blood glucose than to an unspecific stress response. Experiments with isolated perfused rat livers have demonstrated that ethanol has no direct effect on the metabolism of hepatic cAMP.

6230 COMPARISON OF HEPATIC TRIGLYCERIDE CONTENT AND HEPATIC LIPID SECRETION AFTER VARIOUS DOSES OF ETHANOL.

(Eng.) Estler, C. J. (Dept. Pharmacology, Univ. Erlangen-Nurnberg, Erlangen, W. Germany). *Biochem. Pharmacol.* 24(20):1871-1873; 1975.

To investigate the importance of hepatic lipid release in the development of acute alcoholic fatty liver, the effect of ethanol (1, 2, and 4 mg/g, i.v.) on hepatic triglyceride content, hepatic lipid release, and plasma esterified fatty acid levels was studied in female NMRI mice. Within 4-8 hr, all doses of ethanol increased the triglyceride content of the liver to about the same degree. Lipid secretion from the liver was inhibited 2 hr after the administration of 4 mg/g ethanol and increased 8 hr after the injection of 2 and 4 mg/g ethanol. Plasma esterified fatty acids showed an initial increase after 1 mg/g and an initial decrease after 4 mg/g ethanol. Eight hr after the administration of 4 mg/g ethanol, the level of esterified fatty acids in the plasma was increased. Two mg/g ethanol had no effect on plasma esterified fatty acid levels. From the absence of a clear correlation of the three parameters tested, it is concluded that inhibition of lipid secretion from the liver is not a major reason for the development of acute alcoholic fatty liver in mice.

6231 EFFECT OF LONG-TERM ADMINISTRATION OF ETHANOL TO THE RAT: LIPIDS, COLLAGEN AND OTHER PROTEINS, AND MALLORY BODIES IN THE LIVER.

(Eng.) Hakkinen, H.-M.; Franssila, K.; Kulonen, E. (Res. Lab., State Alcohol Monopoly [Alko], Box 350, SF-00101 Helsinki 10, Finland). *Scand. J. Gastroenterol.* 10(8):753-765; 1975.

The effects of long-term ethanol administration and different diet combinations on the growth and liver histology of 6-week-old male Wistar rats were investigated. A control group of 15 rats, who received normal laboratory food and water, showed a mass gain of 4.49 ± 0.23 g/day during their rapid growth period (days 0-39), compared with a gain of 2.78 ± 0.30 g/day for 14 rats on a normal diet who received ethanol (1.20 g/100 g) in their drinking water. A mass gain of 1.85 ± 0.26 g/day was observed in nine rats on a normal diet who received ethanol in the drinking water plus 500 mg/100 g ethanol 3 times/week by stomach tube. Mass gains of 0.80 ± 0.08 g/day were observed in 15 rats receiving a high fat and low protein diet with no ethanol. Fourteen rats on the same diet, but with ethanol in the drinking water experienced a 0.7 ± 0.10 g/day weight gain. The mass gain for 10 rats on a normal diet who received 75 μl carbon tetrachloride/100 g by s.c. injection twice/week was 3.15 ± 0.52 g/day. Histologically, all five rats on a normal diet with ethanol in the drinking water showed mallory bodies in the liver 10 weeks after tratment, and two of three rats on a normal diet who received both voluntary and forced ethanol showed mallory bodies 8 weeks after treatment. Focal and septal inflammation were observed in all seven rats on a high fat, low protein diet without alcohol after 5 and 8 weeks, resp., and in all eight rats on the same diet with ethanol in the drinking water after 4 and 10 weeks, resp. Septal inflammation was observed 8 weeks after treatment in four of five rats receiving carbon tetrachloride (normal diet). Liver fibrosis and cirrhosis were seen in all six rats on a high fat, low protein diet (no ethanol) 10 and 8 weeks, resp., after treatment and in all five rats on the same diet with alcohol in the drinking water after 10 and 16 weeks, resp. Liver cirrhosis was observed 8 weeks after treatment in four of five rats receiving carbon tetrachloride (normal diet). Although both ethanol and the high fat, low protein diet resulted in the development of liver injury, the effects of ethanol in rats receiving the high fat, low protein diet were not enhanced over those observed in rats on a normal diet.

6232 EFFECT OF GLUCOSE ADMINISTRATION ON CHOLESTEROL AND BILE ACID METABOLISM IN RATS.

(Eng.) Uchida, K.; Takeuchi, N.; Yamamura, Y. (Shionogi Res. Lab., Shionogi & Co., Ltd., Fukushima-ku, Osaka 553, Japan). *Lipids* 10(8):473-477; 1975.

Hepatic cholesterogenesis, cholesterol 7α-hydroxylase activity, bile secretion, biliary excretion rates of cholesterol and bile acids, and their compositions were investigated in male Wistar rats given a 50% glucose solution (2 ml/100 g) by stomach tube after fasting for 36-40 hr. Although bile volume was not influenced by glucose administration, the mean biliary excretion of total bile acids increased from a control level of 2.73 mg/hr/100 g to 4.08 mg/hr/100 g ($p<0.05$) 3 hr after glucose administration At this time, the mean rate of hepatic cholesterogenesis (14.88 nmol/hr/g tissue) and cholesterol 7α-hydroxylation (0.93 nmol/hr/mg protein) were also significantly increased over control levels (5.52 nmol/hr/g and 0.36 nmol/hr/mg, resp.) The biliary excretion rate of cholesterol was increased from a mean level of 97 μg/hr/100 g at 0 hr to 119 μg/hr/100 g at 3 hr ($p<0.05$) and 128 μg/hr/100 g at 5 hr ($p<0.05$). The excretion of total bile acids gradually increased from a mean level of 3.20 mg/hr/100 g at 0 hr to 5.16 mg/hr/100 g at 5 hr ($p<0.05$). Gas chromatography of bile acid fractions from fasted controls and glucose-treated rats revealed that the main constituent of biliary bile acid was cholic acid, which comprised 42% in controls and 38% in treated rats. Deoxycholic acid was a minor component in controls, but was increased to about 30% in glucose-treated animals. The excretion of deoxycholic acid in nonfasted, untreated rats was as low as 0.32 mg/hr/100 g, but was almost doubled by fasting (0.69 mg/hr/100 g), and further increased by glucose administration. The highest values were obtained at 1 and 2 hr (1.19 and 1.18 mg/hr/100 g, resp.; $p<0.05$), after which the values decreased gradually to 0.83 mg/hr/100 g at 5 hr. Pretreatment with neomycin (25 mg/100 g daily for 3 consecutive days) abolished the increase in deoxycholic acid by fasting and glucose administration. Other bile acid components showed no significant change. It is presumed that cholesterol endogenously synthesized in the liver is metabolized mainly to cholic acid; in contrast, exogenous cholesterol is metabolized mainly to chenodeoxycholic acid. During the period of the acute enhancement of cholic acid formation from the endogenous cholesterol, biliary excretion of deoxycholic acid was increased. This probably occurs through the depression of 7α-rehydroxylation of deoxycholic acid or through the enhancement of microbial formation of deoxycholic acid in the lumen and through the increase of intestinal absorption.

6233 EFFECT OF ACUTE CHOLESTASIS ON HEPATIC CIRCULATION.

(Eng.) Szabo, G.; Jakab, F.; Magyar, Z. (Natl. Inst. Traumatol., H-1430 Budapest, Mezo Imre ut 17, Hungary). *Acta Med. Acad. Sci. Hung.* 31(3/4):229-239; 1974.

The effect of acute cholestasis on hepatic circulation was studied in 10 mongrel dogs. In each dog, a small mesenteric vein was cannulated with a fine polyethylene catheter whose tip was passed into the portal vein. The cystic duct was ligated, and the common duct was transected and cannulated with a teflon tube. Electromagnetic flow probes were placed on the common hepatic artery and portal vein and were connected to a flow meter. Portal venous and femoral arterial pressures were measured with strain gauges. Control measurements were taken 1 hr after surgery, and the common duct was occluded by connecting the end of the cannula directly to a pressure transducer. Hemodynamic parameters were estimated every 30 min for 6 hr. The common duct was not occluded in three controls. In all dogs, the mean control value for hepatic artery flow was 177 ± 27 ml/min, and for portal vein flow, 439 ± 80 ml/min. The hepatic artery contributed 29% and the portal vein 71% to the total blood flow. Pressure in the common duct was 5.6 ± 0.7 mm Hg before cannulation. After occlusion, pressure rose to 20 mm Hg in 1-1.5 hr. This was followed by an increase in hepatic artery flow, attaining a maximum 95% increase in 2.5-3 hr, accompanied by a slow decrease of portal vein flow to about 50%. Total hepatic blood flow was decreased substantially in the last half hour of the experiment (-13%, $p>20\%$). There was a substantial increase in total portal resistance from 1.75 ± 0.40 peripheral resistance units (PRU) to 6.06 ± 2.73 PRU, while arterial pressure decreased from 51 ± 16 to 26 ± 5 PRU. After 5 hr, the hepatic artery and portal vein flow values were 60% and 40%, resp. There was a significant correlation between the increase in common duct pressure and the changes of arterial and portal vein blood flows ($p<0.1\%$). The relationship between bile duct pressure and blood flow was not linear. There was also no linear correlation between portal blood flow or resistance and arterial flow or resistance; a complex relationship existed. It is concluded that occlusion of the common duct causes a marked increase in hepatic artery flow, reduction of portal vein flow, and little change in total hepatic blood flow.

6234 JAUNDICE AND WOUND HEALING: AN EXPERIMENTAL STUDY.

(Eng.) Bayer, I.; Ellis, H. (Westminster Hosp., London, England). *Br. J. Surg.* 63(5):392-396; 1976.

The effects of obstructive jaundice on the healing of abdominal wounds, gastric incisions, and parietal peritoneal defects were studied in 140 female Sprague-Dawley rats. Obstructive jaundice was induced by ligation and division of the common bile duct. The healing of a standard gastric incision and a parietal peritoneal defect in these animals showed delayed healing compared with controls. There was no significant increase in the mean bursting strength of the abdominal wound in the jaundiced animals between the second and eighth days of wound healing; the strength ranged between 17.90 and 21.20 mm Hg. The bursting strength in controls was significantly higher at days 4 (21.30 mm Hg) and 6 (22.90 mm Hg), and then showed a steep rise between the sixth and eighth days (37.20 mm Hg on day 8). The bursting strength of the gastric incision showed a rapid increase from the fourth to the eighth day in both groups, with no significant difference between the groups. In the controls, the peritoneal defects on the fourth day demonstrated proliferating fibroblasts with commencing collagen deposition. By the eighth day, dense collagen fibers were obvious, had oriented parallel to the surface of the wound, and were interspersed with well-developed and flattened fibroblasts. In the jaundiced rats, the peritoneal defects demonstrated a delay of 48-72 hr in their healing process, so that at 8 days, there was still a considerable cellular exudate containing young fibroblasts with minimal collagen formation. In the jaundiced rats at 8 days, the gastric wound demonstrated granulation tissue in a loose stroma, with necrotic tissue still present and only early fibroblast proliferation, demonstrating considerable histological delay in the healing process. Angiography revealed a delay in angiogenesis in the gastric wounds of the jaundiced animals. It appears that bilirubin or some other substance in retained bile has a profound inhibitory effect on fibroplasia and angiogenesis.

6235 AN ATTEMPT TO INDUCE PORTAL HYPERTENSION AND ESOPHAGEAL VARICES IN THE RAT. (Eng.) Saku, M.; Borjesson, B.; Olin, T.; Bengmark, S. (Dept. Surg., Univ. Lund, S-221 85 Lund, Sweden). *Eur. Surg. Res.* 8(2):166-173; 1976.

Attempts were made to experimentally induce portal hypertension in male Sprague-Dawley rats using Ameroid constrictors and shunt operations. One week after the application of the Ameroid constrictor around the portal trunk, it was completely occluded; portal venous pressure was elevated to 21-27 mm Hg. Angiographically, the splenorenal collaterals and collaterals overbridging the Ameroid constrictor were observed in all examined rats. However, esophageal varices were not found in any rat. In another group of rats, an end-to-side cavoportal shunt was created before the application of the Ameroid constrictor. This operation model was devised to increase the portal venous flow and to inhibit the development of splenorenal collaterals. As expected, collaterals to the superior vena cava system developed instead. However, the collaterals occurred retroperitoneally, not in the esophageal wall.

6236 OXIDATIVE PHOSPHORYLATION IN RAT LIVER MITOCHONDRIA UPON ALIMENTARY COPPER DEFICIENCY AND COPPER LOADING. (Eng.) Kassabova, T. A.; Balevska, P. S.; Roussanov, E. M. (Inst. Physiology, Bulgarian Acad. Science, Sofia, Bulgaria). *Dokl. Bolg. Akad. Nauk* 29(1):117-119; 1976.

The electron transport and oxidative phosphorylation of mitochondria isolated from the livers of Wistar rats were studied during dietary copper deficiency and during copper loading. Copper deficiency was induced by feeding a low-copper diet (powdered milk and redistilled water) for 30 days. Copper loading was produced by feeding a standard diet supplemented with copper sulphate (40 mg/rat/day) for 6 weeks. The copper content in the mitochondria of controls was 0.51 x 10^{-9} M copper/mg protein, while that in the copper-deficient animals was 0.27 x 10^{-9} M and that in the copper-loaded animals was 1.52 x 10^{-9} M. The cytochrome *c* content in copper-loaded animals (0.20 mμM/mg protein) was decreased in comparison to that in controls (0.24 mμM/mg). The cytochrome *c* content in copper-deficient animals was still lower (0.17 mμM/mg). The activity of cytochrome oxidase in copper-loaded animals (1,230 mμAO/min/mg) and in copper-deficient animals (870 mμAO/min/mg) was lower than that in controls (1,480 mμAO/min/mg). During copper deficiency, the liver mitochondria had a lower oxygen uptake in State 3 during the oxidation of all substrates (ascorbate + TMPD, 72.3 mμAO/min/mg; succinate, 107.1 mμAO/min/mg; glutamate + malate, 89.4 mμAO/min/mg; β-hydroxybutyrate, 67.7 mμAO/min/mg) than in controls (92.2, 142.2, 110.6, and 80.4 mμAO/min/mg). The oxygen uptake in state 4 showed no decrease in the oxidation of glutamate-malate, β-hydroxybutyrate, and succinate. The respiratory control index and the ADP:O ratio at the oxidation of these substrates were also lower. This indicates that, in addition to a defect in the electron transport, these mitochondria are characterized by uncoupling, which is probably due to changes in the membrane composition.

6237 EFFECT OF ACETAMINOPHEN-INDUCED HEPATOTOXICITY ON THE METABOLISM AND BILIARY EXCRETION OF [^{35}S]BROMOSULFOPHTHALEIN. (Eng.) Buttar, H. S. (Health Protection Branch, Health and Welfare Canada, Ottawa, Canada). *Toxicol. Appl. Pharmacol.* 33(1):129-130; 1975.

SECRETION AND METABOLISM

Intestine

6259 APOPROTEIN B IN FASTING AND POSTPRANDIAL HUMAN JEJUNAL MUCOSA. (Eng.) Rachmilewitz, D.; Albers, J. J.; Saunders, D. R. (Dept. Medicine, Univ. Washington, Seattle, WA 98195). *J. Clin. Invest.* 57(2):530-533; 1976.

Experiments were conducted to determine whether apoprotein B is present in fasting and postprandial human duodenojejunal mucosa. Duodenojejunal biopsies from 30 normal volunteers were incubated in citrate buffer and were shaken in 1% EDTA to free the absorptive cells from underlying tissue. Apoprotein B was determined by double-antibody radioimmunoassay in homogenates of absorptive cells. The preparations of absorptive cells were uncontaminated with plasma lipoproteins. They adsorbed less than 0.1% of ^{125}I-low density lipoprotein, which was added to the citrate buffer. Cell preparations from suction biopsies of human rectum contained no detectable apoprotein B. Duodenojejunal absorptive cells from 22 fasting subjects contained 3.2 ± 0.5 μg/100 mg apoprotein B (wet weight) or 1.3 ± 0.3 μg apoprotein B per total cell protein. The amount of apoprotein B per milligram of cell protein fell to 0.3 ± 0.1 μg in 14 subjects whose mucosa was also sampled 45 min after intraduodenal fat instillation. These experiments provide immunochemical evidence that human duodenojejunal absorptive cells contain apoprotein B. This technique should be valuable for studying the physiology of intestinal lipoproteins in absorption and in patients with hyperlipidemia.

6260 TRIACYLGLYCEROL BIOSYNTHESIS IN EVERTED SACS OF RAT INTESTINAL MUCOSA. (Eng.) Breckenridge, W. C.; Kuksis, A. (Toronto-McMaster Lipid Res. Clinic, Univ. Toronto, Toronto, Ontario, Canada). *Can. J. Biochem.* 53(11):1184-1195; 1975.

The molecular specificity of the biosynthesis of triacylglycerols by rat intestinal mucosa was examined using radioactive and mass tracers, thin-layer chromatography with silver nitrate, and gas-liquid chromatography with radioactivity monitoring. Bile salt micelles of alternately labeled monoacylglycerols and free fatty acids were incubated with everted sacs of intestinal mucosa for various periods of time, and the triacylglycerols were isolated by solvent extraction and thin-layer chromatography. Analyses of the molecular species of the triacylglycerols labeled from monoacylglycerols showed that the 2-monoacylglycerol pathway was responsible for the biosynthesis of a maximum of 90%, and the *X*-1-monoacylglycerol pathway for about 10% of the total radioactive triacylglycerols. Analyses of the molecular species of triacylglycerols labeled from free fatty acids showed that the phosphatidic acid pathway contributed a minimum of 20-30% of the total labeled triacylglycerol formed. There was a preferential utilization in triacylglycerol biosynthesis of the more unsaturated diacylglycerols arising from the monoacylglycerol pathway and of the more saturated diacylglycerols originating from the phosphatidic acid pathway. The experiments do not allow a demonstration of the utilization of the *sn*-2,3-diacylglycerols in triacylglycerol biosynthesis, but are not inconsistent with it.

6261 ORGANIZATION OF POLYSUBSTRATE PROCESSES ON THE SURFACE OF THE SMALL INTESTINE: PHYSIOLOGICAL AND CLINICAL FINDINGS. (Cze.) Ugolev, A. M.; Gredin, V. G.; Gruzdkov, A. A.; De Laey, P.; Egorova, V. V.; Iezuitova, N. N.; Kolotushkina, A. A.; Timofeeva, N. M.; Tuliaganova, E. Kh.; Tsvetkova, V. A.; Cherniakhovska, M. Yu.; Shcherbakov, G. G. (I. P. Pavlov Inst. Physiology, Leningrad, USSR). *Cesk. Gastroenterol. Vyz.* 28(2):110-121; 1974.

The interaction of the basic groups of nutrients during intestinal absorption and the mechanism and physiological significance of absorption were studied in adult and young rats and adult rabbits, cats, and chickens. Everted sections of the small intestine (excluding the duodenum), tissue homogenates of the small intestinal mucosa and the renal cortex, and solubilized and purified enzymes were used to analyze the hydrolysis of glycyl-L-leucine, glycyl-L-tyrosine, triglycerides, sucrose, maltose, soluble starch, and sodium β-glycerophosphate. Absorption was characterized by the simultaneous processing of different nutrient substrates, and the processes of the polysubstrate digestion interacted in an organized manner. Many of the participating enzymes were allosteric, and enzymes of the same name had different regulatory characteristics in different animal species, in different organs of the same animal, and in the same animal at different periods in the life cycle. The existence of not only catalytic but also regulatory hydrolytic enzymes, and the significance of nutrients not only as substrates but also as modifiers of digestive processes are of practical importance for the understanding and correction of nutritional problems and small intestinal pathology.

6262 EFFECTS OF CHOLERA TOXIN ON ADENYLATE CYCLASE: STUDIES WITH GUANYLYLIMIDODIPHOSPHATE. (Eng.) Flores, J.; Sharp, G. W. G. (Massachusetts General Hosp., Boston, MA 02114). *J. Clin. Invest.* 56(5):1345-1349; 1975.

The effects of cholera toxin and guanylylimidodiphosphate (GIDP) on adenylate cyclase activity were studied in the rat liver. Rats were injected with cholera toxin (1 μg/g, i.v.), and 5 hr later, their livers were perfused through the portal vein with a Tris-HCl buffer. Homogenates from untreated livers were incubated with 4 μg/ml cholera toxin and 1 mM NAD for 15 min. The adenylate cyclase activity in the controls and in *in vivo* and *in vitro* treated homogenates was determined in the presence and absence of GIDP (0-10^{-3} M). In other experiments, homogenates from untreated rats were preincubated with GIDP, and adenylate cyclase was assayed before and after the addition of cholera toxin. In the control preparations, maximal adenylate cyclase stimulation was seen with 10^{-4} M GIDP. Treatment with cholera toxin alone *in vivo* resulted in a sevenfold activation of basal adenylate cyclase. Prior activation of adenylate cyclase by cholera toxin *in vivo* or by cholera toxin and NAD in the homogenates blocked the stimulatory effect of GIDP. Under conditions in which the effect of GIDP was less than that of cholera toxin, inhibition of stimulation by toxin was seen. Stimulation of adenylate cyclase by maximal concentrations of GIDP, but not by submaximal concentrations, blocked the stimulatory effect of cholera toxin. The mutual interference of the actions of these two agents suggests a common target in the regulatory mechanism of the adenylate cyclase complex.

GENERAL

6272 SUBEPITHELIAL CAPILLARY BLOOD FLOW ESTIMATED FROM BLOOD-TO-LUMEN FLUX OF BARBITAL IN ILEUM OF RATS. (Eng.) Csaky, T. Z.; Varga, F. (Univ. Kentucky, Coll. Medicine, Lexington, KY 40506). *Am. J. Physiol.* 229(3):549-552; 1975.

The outflux of ^{14}C-labeled barbital (diethyl barbituric acid) from the blood into the small intestine of Sprague-Dawley rats was measured to determine the subepithelial capillary blood flow in the gut. The small intestine had been perfused with an isosmotic buffer of pH 9.5. Barbital clearance was blood flow-limited when the total blood flow to the small intestine varied between 0.3 and 1.3 ml/min/g wet gut. The barbital clearance amounted to an average of 50.3% of the total blood flow. The total mucosal blood flow, determined by the use of the distribution of microspheres in the layers of gut wall, was 62.76% of the total blood flow. It is concluded that, for anatomical reasons, the subepithelial blood flow available for the transport process is somewhat less than the measured total mucosal blood flow.

6273 EFFECTS OF IRRADIATION ON THE RELEASE AND RETENTION OF LABELLED DNA IN THE SMALL INTESTINE OF MICE. (Eng.) Suciu, D.; Uray, Z.; Abraham, A. D. (Oncological Inst. Biological Res. Centre, luj-Napoca, Rumania). *Strahlentherapie* 150(2):149-153; 1975.

As an extension of studies on the effects of irradiation on the DNA content of the small intestine, male A2G mice were whole-body irradiated with 300, 500, and 800 rads (^{60}Co) at 1 hr and 3 days after receiving an injection of ^{3}H-thymidine (25 μCi, i.p.). The time courses of the total and specific activity of DNA indicated that 3 days after exposure to 500 and 800 rads, the mitotically active cells were selectively lost from the small intestine. The cells that were labeled 1-3 days before exposure were less sensitive to radiation than the cells irradiated 1 hr after the administration of thymidine. The data support the conclusion that the dividing cell population in the small intestine is more radiosensitive than the fraction of functional cells. As the cells migrate from the crypts to the tips of the villi, they lose their proliferative capacity and become more radioresistant.

6274 ELECTROPHORETIC AND IMMUNOCHEMICAL EXAMINATION OF PROTEINS AND SOME ENZYMES OF RAT SMALL INTESTINAL MUCOSA IN THE INTESTINAL TYPE OF RADIATION SICKNESS. (Ger.) Sareckij, A. N.; Kaskin, K. P.; Surinov, B. P. (Res. Inst. Medical Radiology, Obninsk, USSR). *Radiobiol. Radiother. (Berl.)* 15(3):404-417; 1974.

The composition and concentration of small bowel mucosa proteins and enzymes after radiation trauma was explored in male August rats. The microsomes, mitochondria, and hyaloplasma fractions of rat mucosal sections were harvested 6, 12, 24, 48, and 72 hr after whole body ^{60}Co gamma irradiation (total dose, 1,000 R). Electrophoresis found the total protein concentration to be reduced 24 hr after exposure. Some lipoprotein fractions increased, but at a slower rate than the decrease in glycoprotein fractions. A few of the glycoprotein fractions in the deoxycholate extracts went to extinction, probably due to increased lysosomal hydrolase activity. A significant increase in total acid phosphatase activity occurred at 24-72 hr, due to isoenzyme formation. Total aspartic aminotransferase fell gradually, especially the mitochondrial isoenzyme. At 48 hr, the tissue-specific esterase disappeared, corresponding to a marked decrease in acetyl esterase (isoform 1); two species-specific esterases also disappeared. Only trace tissue-specific alkaline phosphatase was detectable. One of the four carboxylesterase isozymes increased by 72 hr, coincident with an elevation in one glycolipoprotein fraction. Certain esterase and lipoprotein fractions also increased by 72 hr. Of the original 26-27 tissue antigens in controls, only 14-15 were demonstrable at 72 hr. No novel radiation antigens were detected, but the data support the distinction between radioresistant and radiosensitive proteins.

6275 A RABBIT MODEL OF PERFORATED APPENDICITIS WITH PERITONITIS. (Eng.) King, D. W.; Gurry, J. F.; Ellis-Pegler, R. B.; Brooke, B. N. (St. Mark's Hosp., London, England). *Br. J. Surg.* 62(8):642-644; 1975.

Attempts were made in rabbits to produce an animal model of peritonitis akin to that found in humans. The base of the appendix was tied with silk thread, leaving the blood supply intact. Using the same incision, laparotomy was performed 18 hr after the first operation. If perforation had not occurred spontaneously, the appendix was incised near the base, allowing the contents to enter the peritoneal cavity. The wound was then closed. Six hours later, appendectomy was performed through the same incision. Twenty-eight of 32 rabbits survived these operations. Twenty of the appendices in the surviving rabbits perforated spontaneously by the time of the second operation. In eight rabbits that lived for at least 14 days and were killed during the third week, necropsy showed a diffuse purulent peritonitis with many adhesions, resulting in multiple abscesses throughout the peritoneal cavity, particularly the caudal half. In 13 rabbits (9 with spontaneous perforation and 4 with artificial perforations), enterobacteria, staphylococci, streptococci, bacilli, lactobacilli, yeasts, bacteroides, bifidobacteria, and clostridia were distributed in a manner similar to that in pus taken at operation in 14 patients with perforated appendicitis with purulent peritonitis. Histologically, the appearances of all the specimens examined were similar and had many features in common with those seen in acute appendicitis in man. However, in the rabbit, suppuration was generally less pronounced and less evenly distributed throughout the wall, and there was a zone of suppurative necrosis extending from the mucosa into the superficial parts of the lymphoid follicles. The latter is not normally seen in humans. It appears that this model is satisfactory for simulating acute perforating appendicitis followed by peritonitis in man, and that postoperative survival is achieved, enabling therapeutic studies to be carried out.

6276 FIBEROPTIC-COUPLED ARGON LASER IN THE CONTROL OF EXPERIMENTALLY PRODUCED GASTRIC BLEEDING. (Eng.) Waitman, A. M.; Spira, I.; Chryssanthou, C. P.; Stenger, R. J. (Beth Israel Medical Center, 10 Nathan D. Perlman Place, New York, NY 10003). *Gastrointest. Endosc.* 22(2):78-81; 1975.

The use of laser photocoagulation for the control of gastric hemorrhage is reported. An argon laser with an output of 2 watts was used in conjunction with conventional fiberoptic endoscopy to control bleeding lesions mechanically produced in the anterior stomach wall of four adult mongrel dogs. Laser irradiation was applied to the experimental sites within 1 min of the onset of bleeding. The photocoagulation process was begun by directing the laser beam to the margin of the defect and by holding the tip of the fiberoptic bundle 2 mm from the surface of the tissue until it produced a charred coagulum. The laser beam was then directed to adjacent areas, working from the periphery to the center until the entire surface of the defect was sequentially photocoagulated. This process required 2-3 min. The time exposure of each individual area treated ranged from 1 to 5 sec, with the central areas of the base of the defect requiring the longest irradiation periods. In all laser-irradiated lesions, hemorrhage ceased immediately upon completion of photocoagulation. Histologic examination of photocoagulated ulcers indicated that morphologic alterations induced by laser irradiation were limited to the target area and did not extend to the muscularis propria or serosa. In laser-irradiated lesions removed 5-30 min after photocoagulation, the vessels in the target area and in the tissues adjacent the margins of the defects contained amorphous yellow-pink material, while the vessels in the surrounding tissue were filled with RBC and marginating WBC. This suggests that circulation was interrupted in the target area, but not in the surrounding tissue, as evidenced by the active process of WBC margination and migration. Sites of photocoagulated ulcers examined 3 weeks after irradiation showed no gross evidence of the lesion, but microscopically, these sites showed reparative changes (almost complete re-epithelization of the surface of former defects and the presence of granulation tissue in the gap of the lesion), which appeared to be more delayed than would normally be expected.

6277 EXPERIMENTS ON MONKEYS WITH CHOLERA TOXIN PARTIALLY PURIFIED AND DETOXIFIED WITH FORMOL AND GLYCINE. (Eng.) Saletti, M.; Ricci, A. (Istituto Sieroterapico e Vaccinogeno Toscano A. Sclavo, Siena, Italy). *Bull. WHO* 51(6):641-645; 1974.

Because previous studies have shown that highly purified cholera toxin detoxified with glutaraldehyde loses its immunizing capacity, and that toxin detoxified with formol reverts *in vivo*, studies were conducted to determine whether cholera toxin partially purified with aluminum hydroxide and detoxified with formol in the presence of glycine remains harmless and retains its capacity to stimulate antitoxins. Rhesus monkeys were divided into seven groups and inoculated with 1-ml doses of toxoid (10, 50, or 100 μg, s.c.), toxin (50 or 100 μg, s.c.), cholera vaccine, or saline. In monkeys inoculated with toxin, a local reaction characterized by erythema and edema appeared on the second or third day after inoculation and lasted for 10-12 days. The animals inoculated with toxoid, vaccine, or saline gave no macroscopic reaction. Histological examination of skin biopsies revealed that toxin at either dose caused edema in the reticular dermal zone, together with phlogistic cellular infiltrates composed of diffused lymphocytes or perivascular accumulation of lymphocytes. Toxoid did not cause any change in the dermis and epidermis, and there was no evidence of edema or hemorrhage. The vaccine produced edema in the entire dermis. After a single dose of 100 μg of toxoid, only one monkey had a detectable antitoxin level (20 AU/ml). After a second inoculation, the two animals treated with 2 x 100 μg toxoid showed total antitoxin levels of 160-250 AU/ml. Of all the monkeys vaccinated with toxoid, only one (inoculated with 2 x 50 μg toxoid) showed a slight skin reaction to a challenge dose of 100 μg of toxin at the inoculum site. All animals inoculated with toxoid showed vibriocidal antibodies 1 month after the first vaccination; the vibriocidal antibodies increased considerably after the second inoculation. The lack of reactivity and the stimulation of antitoxins in monkeys inoculated with cholera toxin partially purified and detoxified with formol in the presence of glycine, can solve the problem of preparing a safe and antigenic cholera toxoid.

6278 EXPERIMENTAL INFECTION OF CHIMPANZEES WITH HEPATITIS A VIRUS. (Eng.) Dienstag, J. L.; Feinstone, S. M.; Purcell, R. H.; Hoofnagle, J. H.; Berker, L. F.; London, W. T.; Popper, H.; Peterson, J. M.; Kapikian, A. Z. (Natl. Inst. Health, Building 7, Room 301, Bethesda, MD 20014). *J. Infect. Dis.* 132(5):532-545; 1975.

The susceptibility of chimpanzees to type A viral hepatitis was examined with immune electron microscopy. Two seronegative infant chimpanzees were inoculated with a hepatitis A acute-phase stool filtrate rich in 27-nm virus-like hepatitis A antigen (HA Ag) particles, and two were inoculated with an HA Ag-negative preinfection stool filtrate. One of each pair of chimpanzees was inoculated i.v., the other p.o. One month later, both chimpanzees that had received the HA Ag-positive filtrate developed elevated SGPT levels, lassitude, and anorexia, suggestive of acute viral hepatitis. HA Ag particles (27 nm) were detected in their stools by immune electron microscopy; particle shedding followed a pattern similar to that in human volunteers. Immune electron microscopy also showed that antibody to HA Ag had developed in the convalescent-phase sera of the infected chimpanzees. Control animals remained free of illness at this time, but did develop hepatitis 3-5 weeks after exposure to the two infected chimpanzees. The infectious inoculum was titrated in two additional seronegative chimpanzees. Hepatitis A can be successfully transmitted to seronegative chimpanzees. These studies provide further evidence that the 27-nm virus-like HA Ag particle is the etiologic agent of viral hepatitis type A.

6279 GROWING SMALL-BOWEL MUCOSA: AN EXPERIMENTAL APPROACH TO THE SHORT-BOWEL SYNDROME. (Eng.) Norton, L. W.; Dogru, M.; Esato, K.; Eiseman, B. (Denver General Hosp., Denver, CO). *Surg. Forum* 26:391-392; 1975.

Experiments were conducted to determine whether small bowel mucosa can grow on muscular or peritoneal surfaces and to devise procedures by which the small bowel absorptive area can be increased. Dogs were placed in one of four groups and subjected to different procedures. In group 1 (5 dogs), a 10-cm segment of transverse colon with vascular pedicle was everted and stripped of mucosa to the level of the muscularis. The reinverted segment was interposed isoperistaltically in the ileum 150 cm proximal to the ileocecal valve. At 6 weeks (3 dogs), the segments of interposed colon had contracted to an average 7-cm length and were lined by mucosa without villi. By 13 weeks (2 dogs), a villous surface pattern was identified. In group 2 (6 dogs), a 20-cm colon segment was similarly interposed in the ileum. In two additional dogs, the segment was divided, and each piece incised along the antimesenteric border. These pieces were anastomosed to create an interposed pouch 10 cm in length with twice the normal colon diameter. Three dogs in this group died due to loss of motility in the segment. The three survivors had neomucosa lining the shortened (30%) segment at 6 weeks. In the two additional animals with widened pouches, mucosa with villi was evident at 13 weeks. In group 3 (5 dogs), a 23-cm segment of colon was stripped of mucosa and divided into longer (20-cm) and shorter (3-cm) portions, each with vascular pedicle. The longer segment was anastomosed end-to-side to the ileum 150 cm from the cecum, and the opposite end was left unclosed within the abdomen as a control. Laterally anastomosed colon segments were shortened (50%) at 6 weeks. In two dogs, the segment was occluded 2 cm from the ileum. Neomucosa had developed proximal but not distal to the obstruction. In three other animals, the segment was completely lined with mucosa at 6 weeks. No mucosa developed in control segments. In group 4 (9 dogs), the ileum was divided 150 cm from the cecum. The proximal end was anastomosed end-to-side to the ileum 100 cm from the cecum. The open end of the distal ileum was sutured to parietal peritoneum over a 4 x 5-cm area. Extension of mucosa across the peritoneum was evident by 3 weeks (2 dogs). By six weeks (3 dogs), the peritoneum was covered by mucosa, which showed early villous formation. Small bowel mucosa has regenerative properties that may be useful in patients with the short-bowel syndrome.

6280 CONGENITAL HYPERTROPHIC PYLORIC STENOSIS: A GASTRIN HYPOTHESIS PURSUED. (Eng.)
Rogers, I. M.; Macgillion, F.; Drainer, I. K. (Royal Infirmary, Glasgow G4 OSF, Scotland). *J. Pediatr. Surg.* 11(2):173-176; 1976.

The hypothesis that the steep rise in fasting gastrin levels seen in neonates produces enough pyloric hold-up in some infants to initiate a self-perpetuating sequence of events leading to hypertrophic pyloric stenosis was tested by determining the effects of pentagastrin and acetylcholine on isolated strips of the pyloric circular muscle of eight baboons. Acetylcholine (1-20 μg/ml) caused a dose-dependent contractile response in all eight strips. This response was blocked by atropine. Pentagastrin (4-10 μg/ml) produced a contraction in four of seven strips tested. Since atropine had been administered to the baboon before the pylorus was taken, it is possible that the inconsistent response to pentagastrin was due to a relative inability of pentagastrin to break the barrier to contraction caused by atropine. The results are compatible with the hypothesis that gastrin plays a part in the development or maintenance of hypertrophic pyloric stenosis in infancy.

6281 STRESS ULCER PREVENTION BY METYRAPONE. (Eng.) Stamford, W.; Smoke, R.; Rettura, G.; Levenson, S. M.; Seifter, E. (Albert Einstein Coll. Medicine, Bronx, NY). *Surg. Forum* 26:371-373; 1975.

The pathogenesis of acute erosive gastritis was studied in male Sprague-Dawley rats. Because endogenous glucocorticoids are thought to have a central role, the actions of metyrapone and vitamin A were studied in rats subjected to a stress ulcer regimen (total body restraint for 24 hr). In some experiments, rats were killed 6 or 12 hr after restraint to observe preulcer changes in the stomach. Multiple large ulcers occurred in the stomachs of all 17 stressed controls and in 3 of 17 animals treated with metyrapone (200 mg/kg in the diet for 3 days prior to restraint). There were seven normal stomachs in the metyrapone-treated animals and none in the controls. Craters were observed in nine controls, but in none of the animals treated with metyrapone. The weight loss among controls was 36 g, while that in the treated animals was 30 g; the thymus weight in controls was 459 mg, while that in the treated animals was 506 mg. Treatment with vitamin A palmitate (150,000 U/kg in diet for 3 days prior to restraint) afforded approximately the same degree of protection as did metyrapone. Rats receiving diets containing both agents were not protected against ulceration to a greater extent than were those receiving only one of the compounds. The serosal side of fixed distended stomachs of the metyrapone- or vitamin A-fed rats was pink, while that of the controls was ischemic and more opaque; this suggests that ischemia precedes ulceration. The protective action of metyrapone in the stress ulcer system may be due to either decreased corticosterone levels or to increased deoxycorticosterone (DOC), which intermediately builds up when 11-β-hydroxylase is inhibited. The similarity in the actions of metyrapone and DOC in other systems suggests that the accumulation of the latter compound contributes to the protective action of metyrapone in stress ulcers. As both DOC and vitamin A are pro-inflammatory, they may be acting to block the actions of glucocorticoids synthesized in response to stress.

6282 EXPERIMENTAL AUTOTRANSPLANT OF THE SMALL INTESTINE IN PIGS: HISTOLOGIC, HISTOENZYMOLOGIC AND ULTRASTRUCTURAL STUDY. (Fre.) Chomette, G.; Cerf, M.: Hay, J.-M.; Preel, J.-L.; Garnier, H. (Groupe hospitalier La Pitie-Salpetriere, 83, boulevard de l'Hopital, 75013, Paris, France). *Ann. Anat. Pathol. (Paris)* 20(4):343-356; 1975.

Orthotopic intestinal autografts were carried out in 22 Large White or Pitman Moore pigs to study the effects of surgery and the ensuing anoxia on the function and histology of the intestinal mucosa. Intestinal function was studied by measuring xylosemia after intraluminal perfusion of 1 g/2 kg of D-xylose via a Thomas intra-intestinal cannula and the presence of lactase, maltase, sucrase, and L-leucyl-β-naphthylamidase in the intestinal mucosa. Absorption of intraluminal instillation of 50 ml of a corn oil emulsion was also observed. Absorption of xylose decreased as did enzyme levels. By day 15, absorption of xylose was normal, but enzyme levels had continued to decrease with some leveling after day 7. Absorption of lipids also decreased and remained low. Animals were sacrificed on days 1, 3, 5, 7, and 15. Conventional histological studies showed a basically unaltered mucosal structure, however, electron microscopy revealed early lymphatic and vascular dilation accompanied by edema and followed by inflammation. There were also discrete but diffuse alterations of the villous enterocytes and of the crypt cells, affecting regeneration and characterized by an abnormally high number of goblet cells. The authors conclude that up to 15th day only gross histological examination of the intestinal mucosa is valuable for detection of immunological rejection of grafts. Biological and ultrastructural studies revealed reaction of the mucosa to surgery and anoxia, maximal on the 7th postoperative day.

6283 RADIOAUTOGRAPHY OF HETEROTOPIC AUTOGRAFTS OF ILEAL MUCOSA IN RATS AFTER PARTIAL ENTERECTOMY. (Eng.) Tilson, M. D.; Livstone, E. M. (Yale Univ. Sch. Medicine, New Haven, CT). *Surg. Forum* 26:393-394; 1975.

The hypothesis that intraluminal chyme plays a role in the initiation of compensatory hypertrophy of the ileum after jejunectomy was tested in 10 Sprague-Dawley rats. Explants of mucosa were removed from the lumen and transplanted beneath the capsule of the kidney after 50% midgut resection and sham-operation. The mean diameter of crypts in the experimental explants was increased 81% over that in the sham explants (131 μ versus 72 μ; $p<0.05$). The mean number of cells per crypt was increased 30% in the experimental group (29.3 versus 22.5; $p<0.001$). The mean number of cells labeled with tritiated thymidine per crypt was increased threefold in the experimental group (11.7 versus 3.7; $p<0.001$), and the percentage of labeled cells per crypt was more than doubled (39.9% versus 16.5%; $p<0.05$). These observations suggest that there is a humoral stimulus for the proliferation of enterocytes after partial enterectomy in the rat.

6284 OPEN PEDICLE GRAFTS OF ILEUM FOR THE REPAIR OF LARGE DUODENAL DEFECTS: AN EXPERIMENTAL STUDY. (Eng.) Gupta, A. K.; Garg, B. K.; Kansal, Y. K.; Sharma, B. D. (Sarojini Naidu Medical Coll., Agra, India). *Br. J. Surg.* 63(3): 241-244; 1976.

The use of open pedicle grafts of ileum for the repair of large duodenal defects was studied in 20 healthy dogs. Full thickness defects were created in the second part of the duodenum by excising a portion of the antimesenteric wall comprising 70-80% of the circumference and measuring 6-9 cm in length. A segment of distal ileum isolated on a mesenteric pedicle was brought to the region of the duodenum through the transverse mesocolon; continuity of the ileum was reestablished by end-to-end anastomosis. The isolated ileal segment was opened along its antimesenteric border to form a full thickness, rectangular patch of approximately the same size as the duodenal defect. Half of the ileal segments were placed in an isoperistaltic direction, and the other half in an antiperistaltic direction. Barium meal examinations, followed by exploratory laparotomy and sacrifice, were carried out at 2, 6, and 12 weeks postoperatively. Two dogs died of peritonitis within 4 days of the operation, and a third had a cardiac arrest immediately following surgery. In the 17 remaining animals, the flow of barium through the duodenum did not seem to be affected by either the isoperistaltic or antiperistaltic patches. The pedicles of the grafts were healthy and intact. There was no ulceration or shrinkage of the grafts. On histologic examination, the healing was good, and the ileal mucosa retained its villi. This study indicates that in large, linear, or circumferential defects of the duodenum the open pedicle grafts of distal ileum are extremely useful.

6285 EFFECT OF SUBDIAPHRAGMATIC VAGOTOMY ON PRODUCTION OF GASTRIC ULCERS IN PYLORUS-LIGATED ALBINO RATS. (Eng.) Ganguly, A. K.; Lal, S. K. (Jawaharlal Inst. Post-Graduate Medical Education, Res., Pondicherry-6, India). *Experientia* 32(1):74-75; 1976.

The effect of complete subdiaphragmatic gastric vagotomy on the production of ulcers was studied in pylorus-ligated rats. In seven animals, the pylorus was ligated, and in nine animals, a subdiaphragmatic vagotomy was followed by pyloric ligation. The mean ulcer index in the rats with an intact vagus nerve was 0.40, while that in the vagotomized animals was 0.039. In the vagotomized animals, the mean volume of the gastric content (3.43 ml) and the mean free acidity of the gastric content (2.44 U) were significantly lower than in the animals with an intact vagus nerve (7.64 ml and 22.14 U, resp.). In the vagus-intact animals, the ulcers occurred in the fundus alone in five cases and in the fundus and body in two cases. In the vagotomized animals, the ulcers occurred in the body alone in six cases and in the body and fundus in one case. The results show that the beneficial effect of vagotomy against the development of ulcers must be due to the reduction in vagus- and gastrin-mediated gastrin secretion.

6286 EXPERIMENTALLY INDUCED CANINE TOXOCARIASIS: LABORATORY EXAMINATIONS AND PATHOLOGIC CHANGES, WITH EMPHASIS ON THE GASTROINTESTINAL TRACT. (Eng.) Hayden, D. W.; Van Kruiningen, H. J. (Mason Research Inst., Worcester, MA 01608). *Am. J. Vet. Res.* 36(11):1605-1614; 1975.

DIAGNOSTIC PROCEDURES

6308 α_1-FETOPROTEIN AND REGAN ISOENZYME IN THE SERUM IN MALIGNANT TUMORS OF THE GASTROINTESTINAL TRACT. (Ger.) Lehmann, F.-G. (No affiliation given). *Z. Gastroenterol.* 14(Suppl.): 268-269; 1976.

Serum regan isoenzyme (RI) of alkaline phosphatase and alpha$_1$-fetoprotein (FP) levels in gastrointestinal malignancy were determined by a variety of methods. In 74 gastric carcinomas, elevated FP was found in 4% by double diffusion (DD), 8% by electrophoresis (EP), 33.3% by passive hemagglutination (PHA), and 16-36% by radioimmunoassay (RIA). In 63 colon carcinomas, the recovery rate was 0% in DD, 2.2% in EP, 11.1% in PHA, and 11.1-42.2% in RIA. In 59 pancreatic carcinomas, 0% was recovered by DD and EP, 33.3% by PHA, and 8.5-21.3% by RIA. In 36 gallbladder or bile duct cancers, FP was identified in 4.2% by DD and EP, 25% by PHA, and 21-50% by RIA. In five small intestinal tumors, EP and DD found 0%, PHA 40%, and RIA 40-60%. In 34 liver carcinomas, DD was 56%, EP 75.4%, and PHA and RIA 100% positive. Nonspecific FP increases up to 2,000 mg/ml in gastrointestinal tumors. Using immune absorbance with insoluble anti-RI-gamma globulin, elevated RI was found in 54% of 13 pancreatic carcinomas, 29% of 31 colon carcinomas, 27% of 11 primary liver carcinomas, 14% in gallbladder or ductal cancers, and 10% of gastric carcinomas. In a prospective study of 264 cirrhotics, FP (by RIA) was found in 11 with clinically unsuspected carcinoma. In posthepatic, postalcoholic, and cryptogenic cirrhosis, the carcinoma incidence was equally high; transient FP was found in 22% of the cases. There is no correlation between serum FP and biochemical variables (GOT, GPT, bilirubin, prothrombin, and gammaglobulin) or clinical stage (compensated cirrhosis, coma, and ascites). A primary liver carcinoma is found in over 10% of subjects with serum FP of 20-2,000 ng/ml.

6309 ANGIOGRAPHY OF THE GALLBLADDER AND BILIARY TRACT. (Eng.) Kaude, J. V.; Hawkins, I. F., Jr. (Univ. Florida Coll. Medicine, JH Miller HC, Box 730, Gainesville, FL 32610). *Semin. Roentgenol.* 11(3):191-195; 1976.

Angiography of the gallbladder and biliary tract is reviewed, and the value of various injection sites and the effect of vasoactive drugs were studied by evaluating 174 injections in 102 patients. Angiography has been utilized only rarely for the primary evaluation of the gallbladder. There are several reasons why it should be used more frequently: cancer of the gallbladder ranks fifth in incidence among all digestive tract cancers; angiographic findings are reliable in diagnosing gallbladder cancer; and early diagnosis of biliary tract cancer is infrequently made by conventional methods. Celiac artery and superior mesenteric artery injections (50 ml at 10 ml/sec) are performed initially to serve as a road map for more optimally selective injections. The hepatic, gastroduodenal, or posterior pancreatoduodenal artery is then selected and catheterized. A relatively high pressure injection (10-12 cm^3/sec) results in good arterial detail. A slow hepatic artery injection (5-6 ml/sec for a total of 50-60 min) usually provides excellent visualization of the gallbladder (arterial, capillary, and venous) and of the liver. Exposures are obtained in anteroposterior, right posterior oblique, and occasionally, left posterior oblique projections. The femoral percutaneous approach is most frequently employed. The gallbladder was visualized in 78% of the 102 patients studied. Visualization was rated on a scale of 0 to 3+, 0 being nonvisualization of the gallbladder wall. The highest rating was 1+ in 35 cases, 2+ in 24 cases, and 3+ in 20 cases. The 0 and 1+ ratings occurred predominately from celiac artery injections without tolazoline. The average ratings for the superior mesenteric artery, celiac artery, or hepatic artery as the injection site were 0.62, 0.68, and 1.4, resp. When celiac artery injection was accompanied by tolazoline or epinephrine, the values were 1.2 and 0.37, resp. When hepatic injection was accompanied with tolazoline or epinephrine, the values were 2.4 and 0.29, resp. A slow hepatic artery injection resulted in an average rating of 1.8, and with tolazoline, the value was 2.9. This study and previous experience show that the gallbladder and biliary tract can be consistently visualized with hepatic artery injection with tolazoline.

6310 EXTRAHEPATIC AND INTRAHEPATIC ANGIOGRAPHY AND PRESSURE MEASUREMENT DURING LAPAROSCOPY. (Ger.) Knoblauch, M.; Funk, C.; Binkert, D.; Lammli, J. (Medizinische Universitatsklinik, Kantonsspital, Ramistrasse 100, CH-8091 Zurich, Switzerland). *Schweiz. Med. Wochenschr.* 104(50): 1886-1887; 1974.

Experiences with angiography (AG) and pressure measurement (PM) via laparoscopic puncture in 19 patients are reviewed. PM in the splenic pulp, intrahepatic portal vein segment, and liver parenchyma represents the pressure in the entire portal region. If all three are identical, there is no thrombosis in the splenic or portal veins. PM in the splenic parenchyma is frequently 1-2 mm Hg higher than in the liver. Since the presentation of indirect, arterial portography in splenomegaly can simulate portal vein thrombosis due to deficient contrast media density, angiographic supplementation is required. Modest splenomegaly often accompanies chronic persistent and subacute necrotizing hepatitis. In three patients, splenic PM was normal, suggesting that persistent viral infection and not elevated portal pressure was responsible. Intrahepatic puncture for AG and PM is of special value in suspected splenic vein or extrahepatic portal vein thrombosis, left hypochondriacal adhesions, and splenectomy follow-up.

6311 ULTRASOUND AND THE GALLBLADDER. (Eng.) Gosink, B. B.; Leopold, G. R. (Veterans Admin. Hosp., 3350 La Jolla Village Drive, San Diego, CA 92161). *Semin. Roentgenol.* 11(3):185-189; 1976.

The use of ultrasound in the diagnosis of gallbladder disease is reviewed. The procedure cannot be satisfactorily performed in the presence of gastrointestinal barium, excessive intestinal gas (as in patients with nonobstructive intestinal distension or intestinal obstruction), or large abdominal dressings that interfere with placement of the transducer. The liver can often be used as an "ultrasonic window" for visualizing the gallbladder, even in the presence of excessive intestinal gas. In these patients, the transducer is positioned over the liver and aimed toward the gallbladder, thus delineating the organ without interference. The patient should be placed on a low-fat meal the evening before the examination, and should take no food or liquids for approximately 12 hr before the procedure. On transverse sections, the normal gallbladder appears as a rounded-to-oval echo-free structure lying along the medial border of the liver just anterior to the right kidney. The normal gallbladder usually measures less than 8 cm in length, but may measure up to 13 cm. Gallstones appear as strong echoes, lying in the most dependent part of the organ. The sound beam usually dose not penetrate beyond the stones due to their high echo-reflecting capability; a relatively echo-free "acoustic shadow" is produced behind the stones. Gallbladder distension is also readily identified by the use of ultrasound. On both transverse and longitudinal scans, the distended common duct can also be frequently seen. Ultrasound examination of the gallbladder and adjacent pertinent structures is a rapid (15-45 min), simple, and noninvasive means of examining this organ. The procedure is safe, and is readily tolerated, even by very ill patients.

6312 CHOLECYSTOKININ CHOLECYSTOGRAPHY. (Eng.) Goldberg, H. I. (Univ. California Sch. Medicine, San Francisco, CA 94143). *Semin. Roentgenol.* 11(3):175-179; 1976.

Studies concerning the use of cholecystokinin (CCK) cholecystography in the detection of abnormal gallbladder are reviewed. The procedure is performed to detect underlying acalculous cholecystitis, partial cystic duct obstruction, and Oddi's sphincter fibrosis in patients presenting with upper quadrant pain whose p.o. cholecystograms have shown good gallbladder function with no evidence of gallstones. The most commonly used CCK dose is 1 Ivy U/kg, and the radiographic position that best presents the full gallbladder profile is the right posterior oblique position. The injection must be given slowly (1-3 min) so that spasm of the gallbladder neck, resulting in obstruction to outflow of contrast material, will not occur and create a false-positive response. A positive CCK cholecystogram is composed of two parts: the patient must reexperience the same right upper quadrant pain and associated symptomatology and the radiographic gallbladder contraction must be less than 20-40%. Among 42 patients who underwent CCK cholecystography in one study, 28 were diagnosed as having cystic duct syndrome, 8 had sphincter spasm or stenosis, and 6 had hypercontraction of the gallbladder. The diagnosis was confirmed surgically in 25 of the 28 patients with cystic duct syndrome and in 4 of 5 patients with sphincter spasm or stenosis. The eight remaining patients with sphincter abnormalities were characterized radiographically by up to 40% emptying of the gallbladder and delayed emptying into the common bile duct and duodenum. In a previously reported study, 18 Of 78 patients undergoing CCK cholecystography had a positive response; 15 had a cholecystectomy, and 14 experienced either complete cure or marked improvement during the follow-up period of 6 months to 4 yr. Most studies indicate that CCK cholecystography is both a useful method to detect acalculous gallbladder or cystic duct disease and that cholecystectomy will help the patient.

6313 SEROLOGICAL DIFFERENTIAL DIAGNOSIS OF VIRAL HEPATITIS IN ADULTS. (Eng.) Hollos, I.; Laszlo, B.; Palfi, A.; Szecsey, Gy.; Novak, E. (Natl. Inst. Public Health, H-1966 Budapest, P.O.B. 64, Hungary). *Acta Microbiol. Acad. Sci. Hung.* 23(1):29-40; 1976.

To study the specificity of the determination of hepatitis A-associated antigen (IHxAg) to the clinical diagnosis of infectious hepatitis (IH, hepatitis A), the sera of 123 IH patients, 177 patients with other liver and/or biliary tract diseases, and 116 patients with serum hepatitis (SH, hepatitis B) were tested for hepatitis B surface antigen (HBsAg) and IHxAg. A complement-fixation microtest was used for HBsAg and the India-ink immune reaction was used for IHxAg. In 401 healthy men living in camps in closed communities, HBsAg was demonstrated in 1.5%. IHxAg occurred in 12.2%, and both antigens occurred in 0.7%. The incidence of HBsAg seems to be age-dependent and influenced by environmental factors. For patients with other liver diseases, the percentages were 10% for HBsAg, 13.5% for IHxAg, and 4.5% for both. Among the IH and SH cases, 14% were positive for both antigens, 10% were positive for neither of the antigens, and 76% were positive for one of the two antigens. In two-thirds of the single-positive cases, the antigen corresponded to the clinical diagnosis. SGPT and thymol turbidity values agreed with the serological findings better than with the clinical diagnosis. The number of days in the hospital appeared to be related to both the serological findings and the clinical diagnosis. The clinical course was the most severe for patients having both antigens in their blood. IHx antibodies from early convalescence were sensitive to 2-mercaptoethanol, whereas those from a later stage were resistant. No correlation was found between the presence of IHxAg and that of the rheumatoid factor. The IHx India-ink reaction was disturbed by the presence of labile serum proteins, while the essentially similar reverse passive hemagglutination reaction was unaffected by them. Testing for IHxAg seems to be a valuable procedure in the differential diagnosis of IH and SH, although previous studies have suggested that the results are more accurate in children than adults.

6314 NEW LABORATORY METHOD TO DETECT HEPATITIS-B (AUSTRALIA) ANTIGEN BASED ON 'ANOMALOUS' LACTATE DEHYDROGENASE ISOENZYME. (Eng.) Baxi, A. J.; Bapat, J. P.; Damle, S. R.; Talavadekar, R. V.;

Rajpal, R. M.; Dave, J. K. (Blood Group Reference Center Unit, Haffkine Inst., Parel, Bombay 12, India). *Vox. Sang.* 31(1):70-73; 1976.

A new laboratory method for the indirect detection of hepatitis B antigen (HBsAg) is described. The method is based on the electrophoretic detection of "anomalous" lactate dehydrogenase (LDH) isoenzyme, which lies between the LDH$_4$ and LDH$_5$ isoenzyme bands on disc electrophoresis in the sera of patients suffering from liver disease. A sandwich technique using 5.8% acrylamide gel is used. The separator gel is allowed to set, after which 0.2 ml of serum diluted with an equal amount of 40% sucrose solution is layered, then, additional acrylamide solution (5.8%) is poured over the serum to create a sandwich. Electrophoresis is performed for 3 hr at 4 C using Tris-glycine buffer at pH 8.3 and a current of 5 ma per gel. After the electrophoretic run, the gel is stained for 15 min with (concentration per ml): lithium lactate (10 mg), nitro-blue tetrazolium (0.4 mg), NAD (1 mg), and phenazine methosulfate (0.05 mg in 0.1 M Tris buffer). Electrophoretic determinations of anomalous LDH were carried out on 90 known positive carriers of HBsAg, as well as on 315 HBsAg negative persons. All of the HBsAg-positive individuals were positive for anomalous LDH, whereas only 22/315 of the HBsAg-negative individuals were positive for the isoenzyme. The method appears to be useful for the detection of HBsAg.

6315 HEPATOMOGRAPHY: AN EXPERIMENTAL TECHNIQUE USING AN EMULSIFIER. A PRELIMINARY STUDY.

(Eng.) Baltaxe, H. A.; Katzen, B.; Alonzo, D. R.; Wixson, D. (New York Hosp.-Cornell Medical Center, 525 East 68th St., New York, NY 10021). *Radiology* 119(1):27-30; 1976.

The effect of two different ethiodized oil emulsions on the liver parenchyma and their value in hepatomography were evaluated in nine dogs. Ten milliliters of an emulsion containing one part of ethiodized oil to one part of dextran 40 and 0.1% sorbitan polyoxyalkalene 80 was injected into the hepatic artery of four animals; 10 ml of another emulsion containing one part of ethiodized oil, three parts of dextran 40, and 0.1% sorbitan polyoxyalkalene 80 was injected in the other five animals. The ethiodized oil particles did not exceed 5μ, and their average size was 1 μ. Prior to injection of contrast medium, liver lesions (1-5 cm) were created in all animals by the injection of polyethylene glycol disterate into the parenchyma during laparotomy. In all nine dogs, opacification of the liver was adequate to obtain diagnostic tomograms; all lesions were well demonstrated. The contrast material, in all cases, was not radiographically detectable in the liver, lungs, or kidneys 36 hr after injection. When the first emulsion was used, retention of the contrast medium was noted radiographically up to 24 hr following injection in arterial vessels with diameters of 60-110 μ. The SGPT level rose above normal values on the first 3 days in six of seven dogs, but returned to normal within 15 days. The contrast medium was excreted by the kidneys, as demonstrated by the opacification of the renal collecting system, but the blood urea nitrogen remained normal and unchanged throughout the experiment. One dog died of liver failure; at autopsy, an inflamed gallbladder was found, and the histology of the liver was consistent with toxic liver damage. All other dogs tolerated the procedure well. Histologic examination of the liver of one animal sacrificed 36 hr after the injection of contrast medium revealed numerous fat vacuoles and polymorphonuclear cells deposited around the small vessels. There was an early, acute vasculitis and a fairly large number of fat droplets in the hepatocytes and Kupffer cells. In the remaining animals, sacrificed 6 weeks to 4 months after the injection, the liver was normal. Although the mechanism of contrast uptake and retention by the liver is uncertain, it is likely that some of the particles are trapped in the precapillary hepatic arterioles and in the capillaries themselves, whereas others are small enough to cross the pulmonary barrier and to enter the kidney where they are retained.

6316 HEPATIC ECHOGRAPHY.

(Eng.) Hebert, G.; Gelinas, C. (Notre-Dame Hosp., 1560 Sherbrooke East, Montreal H2L 4M1 Quebec, Canada). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 125(1): 51-59; 1975.

A differential echographic approach to liver pathology based on dividing echographic patterns into diffuse of localized categories is presented. From these patterns, which may be echogenic or sonolucent, the following liver diseases may be diagnosed: advanced cirrhosis, congenital fibrosis, mild cirrhosis, carcinomatosis, hepatitis, storage disease, myeloid metaplasia, multicystic liver, hepatoma, single necrotic metastasis, abscess with necrotic fragments, single homogeneous metastasis, adenoma, fibroma, and simple cyst. Two particularly useful echographic signs are the attenuation sign and the posterior echo accumulation sign. The attenuation sign indicates a fibrotic pattern, and indicates the cirrhotic nature of a diffuse echogenic pattern. The posterior echo accumulation sign indicates the liquid nature of the liver, and shows the cystic nature of a localized sonolucent pattern.

6317 THE RADIOGRAPHIC DEMONSTRATION OF FATTY LIVER IN CHILDREN (A CLUE TO PROTEIN MALNUTRITION).

(Eng.) Swischuk, L. E.; McConnell, R. F., Jr. (Univ. Texas Medical Branch, Galveston, TX). *J. Pediatr.* 88(3):452-454; 1976.

In a review of patients with conditions known to predispose to fatty infiltration of the liver, seven patients were found in whom the diagnosis of fatty liver was made from roentgenograms of the chest or abdomen. Three patients had malnutrition of kwashiorkor and three had cystic fibrosis; the etiology in the remaining patient was unknown. In fatty infiltration, the liver loses its normal whiteness and becomes grayer or radiolucent. It blends with the normally gray or radiolucent properitoneal fat stripe, and together these structures extend, as a diffuse radiolucency, to the inner edge of the normally more dense abdominal muscles. In fatty infiltration secondary to protein malnutrition, the cytoplasm of hepatocytes is replaced by large intracellular fat droplets that tend to displace the cell nucleus to the side and produce the characteristic signet cell. In acute hepatic necrosis with fatty degeneration, the intracellular fat droplets are microdroplets, which neither greatly distort the cell nor generally replace the cytoplasm. The detection of this subtle roentgenographic finding can provide an early clue to the presence of protein malnutrition.

6318 DIAGNOSIS OF MALIGNANT LIVER TUMORS BY THIN NEEDLE ASPIRATION BIOPSY. (Eng.)

Dominis, M.; Cerlek, S.; Crepinko, I. (Novosel Hosp., Zagreb, Yugoslavia). *Acta Med. Iugosl.* 29(4):307-316; 1975.

The usefulness of fine needle aspiration biopsy in the cytodiagnosis of malignant liver tumors was studied in 54 cases. The biopsy was performed with a 7-10 cm long needle with an inner diameter of 0.7 mm. Primary hepatoma was diagnosed in 13, metastatic hepatoma in 39, and leukemia in 2 patients. Cytologic diagnosis was confirmed by histological preparations in 24 instances and by laparoscopy in 7. Three cases were false positives due to misidentification of small bile ductular cells, which are frequent in cases of cirrhosis. Primary liver tumor cells were usually in groups, with large, polymorphous nuclei containing enormous, dark gray, sharply demarcated nucleoli, making them easily distinguishable from normal liver cells and from those of cirrhotic liver. Tumors metastatic to the liver were divided into five cytological groups. The small round type of malignant cell had small, round nuclei with hyperchromic, irregular chromatin and scanty, basophilic cytoplasm. The large type of malignant cell had irregular, meshlike chromatin with large, pale, irregular nucleoli; the cytoplasm was faintly blue and irregular. The cylindric malignant cells always occurred in clusters or papillary structures. They were oval, with dense, coarse chromatin and no visible nucleoli; the cytoplasm was scanty and pale blue. Polymorphic cells had large, oval, round, or irregular nuclei, with coarse chromatin and many irregular nucleoli. Pigmented melanoma cells had oval nuclei with very fine, delicate chromatin, and a sharply defined nucleolus. The cytoplasm contained dark green and brownish pigment granules. It is concluded that the technique is useful and reliable.

6319 OPERATIVE AND ENDOSCOPIC PANCREATOGRAPHY IN THE DIAGNOSIS OF PANCREATIC CANCER.

(Eng.) White, T. T.; Silverstein, F. E. (Dept. Surgery, RF-25, Sch. Medicine, Univ. Washington, Seattle, WA 98195). *Cancer* 37(1):449-461; 1976.

Two years of experience with endoscopic retrograde cholangiopancreatography (ERCP) as a method of obtaining x-rays of the pancreas without surgery are reviewed. The pancreatic duct can be visualized in 85-90% of patients. This test is used to detect pancreatic carcinoma in the symptomatic patient and to search for an operative pancreatic lesion in a patient with known recurrent or chronic pancreatitis. Many of these patients have pain or a transiently elevated amylase; a few have steatorrhea or abnormalities of the duodenal sweep on barium meal examination. Stenosis or obstruction of the main pancreatic duct, with or without proximal duct dilation, are the characteristic abnormalities noted in pancreatic carcinoma. A rare pancreatic tumor not in juxtaposition with the duct will have a normal pancreatogram, although the common duct may be obstructed as determined by cholangiography as it passes through the head of the pancreas. In patients with chronic pancreatitis, it may be difficult to differentiate an inflammatory from a neoplastic stricture by either operative or endoscopic pancreatography. In the future, cytologic and biochemical examination of the pancreatic secretions obtained at ERCP may increase the accuracy of diagnosing carcinoma.

6320 DOUBLE-CONTRAST EXAMINATION OF THE SMALL BOWEL WITHOUT INTUBATION. (Ger.)

Novak, D. (Rontgenabteilung der Radiolog. Univ.-Klinik, Universitats-Krankenhaus Eppendorf, Martinistrasse 52, 2000 Hamburg 20, W. Germany). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 125(1):38-41; 1976.

A simple method of oral double contrast examination of the small intestine without intubation is described. Approximately 200 ml of barium sulfate suspension are administered in 15-20 min after the end of gastroduodenal radiology. The patient—preferably lying on the right side—then receives an additional 50 ml of barium sulfate plus six soluble capsules containing 0.6 g of a mixture of tartaric acid, sodium hydrogen carbonate, and dimethylpolysiloxan. On dissolution, the effervescent powder leads to bubble-free CO_2 formation. The consequent dilation of the intestine stimulates propulsion peristalsis. After presentation, 2 mg of glucagon achieves hypotonia. The technique was applied to 130 patients, 17-76 yr old, with tumor suspicion or regional enteritis. Mean passage time was 78 min, contrasted with 126 min in 83 control subjects. Double contrast was achieved in 90 cases. There were no side effects or subjective complaints. The method's advantages are the accelerated media passage with simultaneous presentation of the entire small intestine and better resolution of interior detail.

6321 CLINICAL SIGNIFICANCE OF SMALL INTESTINAL PHOSPHATASE IN THE SERUM. (Ger.)

van Husen, N.; Eberhardt, G.; Gerlach, U.; Oberwittler, W. (Med. Klinik und Poliklinik der Universitat, 44 Munster, Westring 3, W. Germany). *Med. Welt* 26(37): 1645-1647; 1975.

The clinical role of serum alkaline phosphatase (SAP) from the small intestine of patients with chronic liver disease was compared with that of other hepatic metabolic variables. The clinical sample included 16 patients with fatty liver (FL), 26 with chronic active hepatitis (CAH), and 33 with cirrhosis (CR). SAP was increased 13% in FL, 19% in CAH, and 36% in CR. A statistically significant negative correlation between increased SAP and serum cholinestarase was obtained for CAH ($p<0.05$) and CR ($p<0.001$); cholinesterase activity decreases as SAP increases. Gamma-globulin correlated positively with SAP in CAH and CR, confirming the clinical observation that elevated globulin can be pathognomic of liver insufficiency. No correlation was found with serum albumin or prothrombin. The frequency of high SAP correlated well with elevated serum bilirubin ($p<0.01$), delayed bromothalein retention ($p<0.01$), or increased serum leucine aminopeptidase ($p<0.05$) in CAH. An inverse correlation resulted with SGPT in CR. Elevated SAP is a relatively rare occurrence in FL patients. No inference about isoenzyme pattern and no pathophysiological explanations of elevated activity can be drawn from the total SAP assay.

6322 THE ROLE OF URINARY INDICAN AS A PREDICTOR OF BACTERIAL COLONIZATION IN THE HUMAN JEJUNUM.

(Eng.) Mayer, P. J.; Beeken, W. L. (Dept. Medicine, Univ. Vermont, Burlington, VT 05401). *Am. J. Dig. Dis.* 20(11):1003-1010; 1975.

The usefulness of urinary indican as a predictor of bacterial colonization in the human jejunum was evaluated in 35 patients with various gastrointestinal diseases and in 5 controls. Indican excretion ranged from 1 to 840 mg/24 hr in subjects with normal jejunal cultures and from 18 to 742 mg/24 hr in patients with colony counts above 10^4/ml. Neither tryptophan absorption nor fecal nitrogen excretion correlated with indican excretion ($r=0.18$ and 0.04, resp.). There was a statistical correlation between protein loss and urinary indican ($r=0.54$), with endogenous protein loss being abnormal in 27/37 subjects and in 20/29 with high indican values. Lactose tolerance tests and D-xylose, B_{12}, and fat absorption tests showed no predictive value for identifying patients with high colony counts. Compared to quantitative small bowel cultures, none of the tests examined provided a suitable method for screening for bacterial contamination of the human jejunum.

6323 THE APPLICATION OF A COMBINED XYLOSE-LACTOSE TOLERANCE TEST IN CHILDREN WITH SUSPECTED MALABSORPTION.

(Ger.) Brugmann, G.; Niessen, K. H.; Schmidt, K.; Hontzsch, D. (Kinderklinik der Univ. Rumelinstr. 23, D-7400 Tubingen, W. Germany). *Monatsschr. Kinderheilkd.* 124(2):54-58; 1976.

The diagnostic value of serum glucose levels, supplementary to xylose concentrations in describing the status of the small bowel mucosa after xylose-lactose loading in the pediatric malabsorption syndrome was explored. The test included 2 g/kg lactose and 0.5 mg/kg xylose in 20 ml of tea, up to maximum of 50 g lactose and 25 g xylose. Serum was assayed before the test (fasting) and 15, 30, 45, 60, and 90 min afterward, and the results were supplemented by duodenal biopsy. There were 44 patients with normal villi (group A), 12 with injured villi (group B), and 12 with atrophied villi (group C). The fasting values were approximately equivalent in the three groups. At 15 min, the average serum xylose concentration in group A was 15.8 mg/100 ml; in group B, 12.3; and in group C, 7.7. At 45 min, group A had a serum xylose concentration of 28.2 mg/100 ml; B, 20.6; and C, 11.7. At 90 min, A was 34.0 mg/100 ml, B, 30.8, and C, 15.6. Maximum serum glucose concentrations were 55.8 mg/100 ml for A, 27.3 for B, and 17.7 for C. The xylose values alone would be useful in minimizing, without risk, the number of biopsies in cases of suspected celiac disease. In general, discriminant analysis found the overlap between groups to be too extensive to justify setting normal and abnormal limits. The glucose elevation was also found to be clinically negligible, and in agreement with the literature consensus, its routine assay appears unwarranted.

6324 STATISTICAL STUDY OF THE VALIDITY OF THE D-XYLOSE TEST IN THE DETECTION OF PROXIMAL SMALL INTESTINE LESIONS. CHOICE OF DISCRIMINANT PARAMETERS AND THEIR CUT-OFF VALUES.

(Fre.) Mary, J.-Y.; Aymes, C.; Rambaud, J.-C. (Groupe de Recherches sur la Physiopathologie de la Digestion, INSERM, U-54, Paris, France). *Biol. Gastroenterol. (Paris)* 8(4):297-305; 1975.

The validity of the D-xylose test (25 g dissolved in 250 ml of water, imbibed *ad lib*), the most discriminative parameters and their cut-off values were evaluated from a statistical study of 106 control subjects and 26 patients with circumscribed (13) or disseminated (13) small intestinal lesions. Of the 26 patients, 18 had celiac disease, 2 had intestinal lipodystrophy, 4 had undergone jejuno-ileal resection, and there was 1 case each of alpha chain disease and erosive ileitis. D-xylose was measured in the blood (g/l) at 2 and 5 hr, and in the urine (g/ml) between 0 and 2 hr and 2 and 5 hr. Two protocols were deduced from the results. The first method employs the discriminative linear function of blood xylose at 2 hr (S_2) and 5 hr (S_5). By this protocol, 98.4% of the patients with lesions fell under a calculated value (-0.16) and 93.7% of the controls were above the value. For the second procedure, blood xylose was calculated at 2 hr (S_2) and urine xylose was determined within the first 5 hr (U_T) after oral overload. By this method, 90.3% of the patients with lesions and only 3.3% of the controls had S_2 and U_T values, simultaneously, under 0.025 g/l and 4 g, resp. The two methods are comparable for detecting lesions of the proximal small intestine; both include the kinetics of the appearance and disappearance of sugar in the extracellular. The first method is advantageous in that it requires only two blood measurements; however, it does require complex calculations.

6325 ENDOSCOPIC POLYPECTOMY OF THE JEJUNUM. (Eng.) Montori, A.; Viceconte, G.; Miscusi, G.; Viceconte, G. W.; Pastorino, C. (3rd Surgical Clinic, Rome Univ., Digestive Endoscopy Center, Italy). *Endoscopy* 7(4):249-250; 1975.

The case of a 44-yr-old man in whom endoscopic polypectomy for the removal of a jejunal lipoma was successfully performed is presented. A Billroth II gastric resection for duodenal ulcer had previously been performed in the patient. He presented with intestinal obstruction, and an x-ray revealed a tumor situated about 20 cm from the anastomosis in the efferent loop. The polyp, which later proved to be a fibrolipoma, was removed with a diathermic snare, using a panendoscope. The patient made an uneventful recovery.

6326 ARTERIOGRAPHIC DEMONSTRATION AND COLONOSCOPIC REMOVAL OF A BLEEDING JUVENILE POLYP. (Eng.) Stillman, A. E.; Long, P.; Komar, N. N. (Tucson Medical Center, Tucson, AZ). *J. Pediatr.* 88(3):445-446; 1976.

The case of an 8-yr-old boy in whom a bleeding polypoid lesion was demonstrated by mesenteric arteriography and removed transcolonoscopically is reported. The patient presented with rectal bleeding. The rectal examination was normal. At sigmoidoscopy, large quantities of blood were seen descending from above the reach of the sigmoidoscope (22 cm), and at least 300 ml of blood were aspirated during the procedure. Mesenteric arteriography was performed immediately, and this revealed a polypoid lesion in the mid-descending colon. The bleeding stopped shortly after arteriography. The polyp was successfully removed using electrocautery via colonoscopy. This case demonstrates that under selected conditions, transcolonoscopic polypectomy may assist in the management of pediatric patients with polypoid lesions.

6327 RADIOGRAPHIC EVALUATION OF PANCREATICOJEJUNAL SHUNTS. (Eng.) Miller, E. W.; Goldberg, H. I.; Goldberg, S. B.; Shapiro, H. (750 Las Gallinas Ave., San Rafael, CA 94903). *Scand. J. Gastroenterol.* 1(2):439-443; 1976.

A postsurgical radiographic evaluation of pancreaticojejunal shunts was performed in two patients using a fiberoptic panendoscope with retrograde injection via the ampulla of Vater. The first patient was a 34-yr-old man with a long history of drug abuse and of alcoholism. An endoscopic retrograde cholangiopancreatography (ERCP) was performed, which revealed a massively dilated main pancreatic duct and side branches typical of chronic pancreatitis. A pancreaticojejunostomy with Roux-en-Y jejunojejunostomy and a cholecystectomy were performed. Five months later, there was a recurrence of upper abdominal distress, and a repeat panendoscopy with ERCP was carried out. Injection of contrast medium rapidly filled a dilated, ectatic ductal system. The contrast medium entered the jejunal loop and readily spilled from the pancreatic duct into the jejunum through the Roux-en-Y anastomosis. The recurrence of the patient's symptoms was found to be due to a resumption of drinking, and the patient was instructed to stay away from alcohol entirely. The second patient, a 49-yr-old woman with a long history of chronic pancreatitis, presented with severe abdominal pain. A partial resection of the body and tail of the pancreas was carried out with a pancreaticojejunostomy and a Roux-en-Y jejunum-to-jejunum drainage. One year later, an ERCP was performed because of pain and weight loss. The contrast medium filled the pancreatic ducts satisfactorily, but the main pancreatic duct appeared moderately dilated, and there was a narrowing at the pancreaticojejunal anastomosis. Total pancreatectomy, choledochojejunostomy, and a revision of the Roux-en-Y jejunal anastomosis were performed, and the patient improved. The results in both cases show the value of endoscopy and retrograde injection of the pancreatic duct.

6328 USE OF A STEERABLE CATHETER FOR INTUBATING PATIENTS WITH ZENKER'S DIVERTICULUM. (Eng.) Doods, W. J.; Miller, W. N.; Hogan, W. J.; Stewart, E. T.; Arndorfer, R. C. (Milwaukee County Medical Complex, 8700 West Wisconsin Ave., Milwaukee, WS 53226). *Am. J. Dig. Dis.* 21(1):47-48; 1976.

Because esophageal or gastric intubation attempts often fail in patients with Zenker's diverticulum, a steerable-catheter technique was developed and is described. During fluoroscopy, the soft steerable catheter (which can be manipulated by a control handle connected to 4 longitudinal wires embedded in the catheter wall) tip is aligned with the upper esophageal sphincter and is subsequently advanced into the cervical esophagus. Following esophageal catheterization, a guide wire is passed through the catheter into the distal esophagus or stomach. After removal of the steerable catheter, any type of tube may be passed over the guide wire into the esophagus. This technique was successfully used in six patients with Zenker's diverticulum in whom the conventional methods for placing a manometric tube in the esophagus were unsuccessful. The tube was positioned in less than 10 min, and the procedure was well tolerated. This method may also be used for negotiating the lower esophageal sphincter in achalasia patients with a tortuous megaesophagus.

6329 THE VALUE OF THE LEUKOCYTE COUNT IN THE DIAGNOSIS OF ACUTE APPENDICITIS. (Eng.) Raftery, A. T. (Leeds General Infirmary, Leeds, England). *Br. J. Surg.* 63(2):143-144; 1976.

To determine the value of the WBC count in the diagnosis of acute appendicitis, total and differential WBC counts were performed on 175 patients with a provisional diagnosis of acute appendicitis. Ninety-six percent of 106 patients with acute appendicitis had either an abnormal total or differential WBC count (>10,000 mm^3). Four of 24 patients operated on with a normal count had acute appendicitis. It is concluded that leukocytosis of above 10,000 mm^3 or a differential in excess of 75% neutrophils supports the clinical diagnosis of acute appendicitis and that routine estimation of the WBC count is a useful investigation. While a normal count does not exclude even a perforated appendicitis, such a count should prompt further review of the diagnosis, especially in the presence of an atypical history or minimal physical signs.

6330 DOUBLE CONTRAST BARIUM MEAL EXAMINATION—A COMPARISON OF TECHNIQUES FOR INTRODUCING GAS. (Eng.) James, W. B.; McCreath, G.; Sutherland, G. R.; McDonald, M. (Southern General Hosp., Glasgow, Scotland). *Clin. Radiol.* 27(1): 99-101; 1976.

A comparison between techniques for introducing additional gas to the stomach for double contrast barium examination was made in 250 patients. The patients were divided into five groups and received one of the following treatments: one teaspoon effervescent powder; 60-100 ml tonic water; 15-20 effervescent tablets; transnasal intubation of 100-150 ml of air; or no treatment, but swallowed air. The administration of effervescent tablets was associated with significant improvement in gastric mucosal coating ($p<0.05$) and significantly less bubble formation ($p<0.01$). The effervescent powder was associated with significantly greater bubble formation ($p<0.01$). Effervescent tablets appear to be the method of choice for introducing gas into the stomach in double contrast barium meal examinations.

6331 A NEW RADIOISOTOPIC TECHNIC FOR THE MEASUREMENT OF GASTRIC EMPTYING TIME OF SOLID MEAL. (Eng.) Chaudhuri, T. K.; Greenwald, A. J.; Heading, R. C.; Chaudhuri, T. K. (Hampton Veterans Admin. Hosp., Hampton, VA 23667). *Am. J. Gastroenterol.* 65(1):46-51; 1976.

The suitability of using technetium-99m-diethylene triamine penta-acetic acid (^{99m}Tc) chelate as a marker in determining the gastric emptying rate of a solid meal was tested in four dogs, eight normal human subjects, and *in vitro*. In addition, a standard value for normal gastric emptying, $T_{1/2}$ of solid meal, was established using this substance and a gamma camera-computer system. In dogs fed ^{99m}Tc in 250 ml of normal saline, about 0.5% of the radioactivity was recovered from the total blood and urine, and about 0.1% was recovered from the thyroid and kidneys. Approximately 96% of the administered radioactivity was retrieved from the gastrointestinal content. The stomach had only about 1% activity. These results indicate insignificant absorption and adsorption of ^{99m}Tc. The urine and blood activity (<0.5%) in human subjects also revealed insignificant absorption of ^{99m}Tc. To assess the adsorbability of ^{99m}Tc to the test meal (cornflakes), a mixture of cornflakes, milk, ^{99m}Tc, and human gastric juice was centrifuged, and the supernatant was counted for radioactivity. About 20% of the radioactivity was left over in the supernatant, in comparison with 40% in a similar experiment using ^{51}Cr-sodium chromate. These results indicate less adsorption of ^{51}Cr to cornflakes, which is not desirable. Using the gamma camera computer system, the gastric activity in % in the stomachs of human volunteers after ingesting the test meal plus 500 µCi of ^{99m}Tc could be plotted against time on semilog paper. The $T_{1/2}$ of a radiolabeled solid meal from the stomach was calculated and was found to be a mean of 37 min. The gastric emptying curve was monoexponential, at least for the first 60 min. The $T_{1/2}$ in this study is lower than those reported in other studies (56, 70, and 68 min). The difference may be explained by differences in the technique, radioisotope, and meal composition. ^{99m}Tc appears to be a suitable marker for gastrointestinal studies.

6332 EFFECT OF NICOTINE ON THE PRODUCTION OF GASTRIC ACID. (Ger.) Mertz, D. P.; Thongbhoubesra, T. (Kurklinik am Park, 4934 Bad Meinberg 2, Postfach 2129, W. Germany). *Med. Klin.* 71(4):147-155; 1976.

The effect of nicotine on the ionic composition and amount of gastric secretion during maximal or submaximal acid stimulation was explored in smokers and nonsmokers. The subjects included 20 fasting men, 27-58 yr old, and 5 fasting women, 33-50 yr old. Submaximal stimulation was elicited by betazole (50 mg/hr, i.v.) in 13 persons (group A), and maximal stimulation was elicited by betazole (2 mg/kg/hr, i.v.) in 12 persons (group B). After secretory baselines were established, nicotine hydrogen hydrate was administered in the following doses: 0.012-0.020 mg/kg to seven nonsmokers in group A, 0.022-0.034 mg/kg to six smokers in group A, 0.018-0.032 mg/kg to seven nonsmokers in group B, and 0.033-0.048 mg/kg to five smokers in group B. These doses are above the threshold, but well below toxicity. The concentration of all electrolytes in group A changed significantly. H^+ and Cl^- rose an average 7% and 5%, resp., over base levels. The concentration of Na^+ and K^+ fell an average 21% and 9%, resp. Differences between smoker and nonsmoker responses in group A were insignificant. The rate of gastric juice and ion secretion was unaffected by nicotine in groups A and B. In group B, H^+ increased 5% and K^+ decreased 7%; Na^+ and Cl^- were unchanged, on the average. The secretory rate of H^+ also rose. Various clinical and experimental outcomes of nicotine-induced elevations in gastric acidity and consequent embarrassment of the mucosal barrier are reviewed.

6333 PERORAL STAINING METHOD WITH TOLUIDINE BLUE AS AN AID IN THE DIAGNOSIS OF MALIGNANT GASTRIC LESIONS. (Eng.) Giler, S.; Kadish, U.; Urca, I. (Beilinson Medical Center, Petah Tiqva, Israel). *Am. J. Gastroenterol.* 65(1):37-40; 1976.

The accuracy of the toluidine blue staining method in the diagnosis of malignant gastric lesions was evaluated in 42 patients with suspected lesions. Following removal of gastric mucus, the mucosa was exposed to the action of the dye by having the patients drink 500 ml of acetate buffer containing 16-20 mg of chymotrypsin. Toluidine blue (500 mg) was then administered in capsule form. Twenty-four hours later, endoscopy was performed. Thirty-three patients were operated upon after second staining. Of these 33, 18 had malignant lesions. Positive staining was recorded in 15 of them. Ten of 11 malignant tumors and 5 of 7 ulcers with malignant changes were stained. Only 1 of 13 benign lesions showed positive staining. Of the three unstained malignant lesions, two occurred in the only two patients who vomited the dye immediately following administration. The results indicate that the use of toluidine blue staining prior to endoscopy might be helpful in demonstrating minute malignant lesions of the gastric mucosa and in determining the most likely site for obtaining a positive biopsy. It can also be helpful in the differential diagnosis of benign and malignant ulcers in the stomach.

6334 DEMONSTRATION OF EROSIVE GASTRITIS BY THE DOUBLE-CONTRAST TECHNIQUE. (Eng.) Poplack, W.; Paul, R. E.; Goldsmith, M.; Matsue, H.; Moore, J. P.; Norton, R. (Tufts-New England Medical Center Hosp., 171 Harrison Ave., Boston, MA 02111). *Radiology* 117(3):519-521; 1975.

Experience with the routine use of a pharmacologically-aided double-contrast (PDC) method of roentgenographic visualization for the detection of superficial gastric erosions is presented. The patient receives 0.5 mg of glucagon, i.v., and then ingests 30 ml of barium. Approximately 4 g of gas-releasing powder, followed immediately by 8 ml of water containing a silicone antifoaming agent, is administered p.o. The prone patient is turned side to side to coat the anterior mucosal wall, and spot films are taken. The patient is placed upright, receives an additional 207 ml of barium, and is placed in the supine position for additional films. Among 1,800 upper gastrointestinal examinations, changes characteristic of erosive gastritis were seen in 10 patients. In six cases, endoscopy clearly confirmed the diagnosis. In all cases, the central punctate barium collections were superimposed on edematous nodules of gastric mucosa, either grouped in small clusters or isolated to form small, relatively flat polypoid lesions. It appears that erosive gastritis is more common than generally believed. The diagnosis requires relaxation of the stomach and demonstration of fine mucosal relief by the double-contrast technique.

6335 RESIDUAL BILIARY CALCULI: DISPERSAL BY IRRIGATION OF COMMON BILE DUCT. (Eng.) Mackie, B.; Frachowiak, R. S. J.; Cembala, J. A. (Salisbury General Hosp., Salisbury SP2 7SX, England). *Br. Med. J.* 4(5999):737-738; 1975.

A recently developed washout technique for the dispersal of residual biliary duct calculi is described, and the case reports of two patients in whom it was successfully used are presented. Before starting the procedure, bile is cultured and, if infected, the patient is given the appropriate antibiotic. The washout is performed by connecting the T-tube to 1 liter of sterile 0.9% saline, to which 40 ml of 1% lignocaine has been added. Propantheline (15 mg bromide, i.m.) is given 30 min before the start of the irrigation. T-tube choledochogram showed no evidence of calculi after this procedure in the two patients; in both patients, the residual stones had been located in the lower end of the duct. The evidence supports the argument that nonsurgical procedures have a significant place in the management of patients with residual stones, particularly if they are in the lower portion of the bile duct.

6336 CLINICAL VALUE OF GASTRIN DETERMINATION. (Pol.) Zaborowski, P.; Grabowski, T.; Bogoniowska, Z. (IV Kliniki Chorob Wewnetrznych Instytutu Medycyny Wewnetrzneg WAM, 04-349 Warsaw, ul. Szaserow 128, Poland). *Pol. Tyg. Lek.* 31(25): 1061-1063; 1976.

GASTROINTESTINAL DISEASES

ESOPHAGUS

6381 RETROGRADE OESOPHAGOSCOPY VIA GASTROSTOMY. (Eng.) Hentschel, E.; Dittrich, H.; Weiss, W. (First Med. Dept., Hanusch-Krankenhaus, Vienna, Austria). *Endoscopy* 8(1):38-40; 1976.

The case of a patient in whom a benign stenosing esophagitis was diagnosed using retrograde esophagoscopy via a gastrostomy is presented. The patient, a 66-yr-old woman with an esophageal diverticulum, presented with vomiting. An x-ray examination showed a widened esophagus; the cardiac orifice was closed by a stenosing process. An exact diagnosis was difficult because of stasis of food, and barium did not pass into the stomach. The introduction of a fiberscope failed because the patient did not cooperate, and rough manipulation with the instrument could not be carried out because of the diverticulum in the upper esophagus. A gastrostomy was performed to prepare the patient for stenosis removal by intensive enteral and parenteral nourishment. Eight days later, a fiberscope was introduced into the stomach through the gastrostoma. A severely inflamed mucosa with peptic ulcerations and necrosis was seen about 1 cm above the cardiac orifice. No signs of malignancy were found.

6382 TRANSHEPATIC EMBOLIZATION OF ESOPHAGEAL VARICES. (Fre.) Doyon, D.; Mouzon, A.; Vadrot, D.; Franco, D.; Bismuth, H. (Hopital de Bicetre, 78, avenue du General-Leclerc, 94270 Kremlin-Bicetre, France). *J. Radiol. Electrol. Med. Nucl.* 56(12):917-921; 1975.

A technique for the embolization of the gastric coronary vein and posterior gastrics is described for arresting hemorrhage from the esophageal varices. The technique is recommended for cirrhotic patients when the presence of hepatic insufficiency contraindicates a portal by-pass operation. Embolization is carried out by injecting fragments of Songel, followed by injection of a mixture of coagulants (Thrombase and Hemocaprol). The liver is punctured with the patient anesthetized, and the coronary vein approached by the transportal system or the umbilical vein (under radiographical control). Failure may occur as a result of an unfavorable anatomical disposition of the coronary vein. Case reports of two of six successful embolizations in hemorrhaging patients, are included. No complications occurred in any of the cases.

6383 RETURN OF ESOPHAGEAL PERISTALSIS IN IDIOPATHIC ACHALASIA. (Eng.) Mellow, M. H. (Coll. Physicians Surgeons, Columbia Univ., New York, NY). *Gastroenterology* 70(6):1148-1151; 1976.

The response of a 54-yr-old man with idiopathic achalasia to multiple doses of a direct-acting cholinergic agent was compared to that of eight other achalasia patients and eight controls. Achalasia had been diagnosed 7 yr previously, and pneumatic dilation had provided a good clinical response. At 7-yr follow-up, features considered typical of achalasia were no longer present, and a return of peristaltic activity throughout most of the body of the esophagus was seen. The subject, controls, and achalasia patients received three doses of bethanechol (1, 1, and 2 mg, s.c., at 5-min intervals). The maximal lower esophageal sphincter (LES) pressure recorded was used as the LES pressure response to each dose. The LES response of the subject and the controls differed significantly from that seen in the achalasia patients ($p<0.01$ at each dose). The mean percentage of relaxation in the subject under baseline conditions was 54%. The percentage of relaxation with swallowing was unaltered after bethanechol (47, 53, and 41% at each dose). Administration of bethanechol resulted in a sustained intraesophageal pressure increase to greater than 25 mm Hg in all achalasia patients. Neither the controls nor the subject had an intraesophageal pressure increase. The response of the subject represents the first reported case of the return of esophageal peristalsis in idiopathic achalasia.

STOMACH

6414 A HIGH-POWER GASTRIC PHOTOCOAGULATOR FOR FIBEROPTIC ENDOSCOPY. (Eng.) Auth, D. C.; Lam, V. T. Y.; Mohr, R. W.; Silverstein, F. E.; Rubin, C. E. (Center Bioengineering, Univ. Washington, Seattle, WA 98195). *IEEE Trans. Biomed. Eng.* 23(2):129-135; 1976.

A fiberoptic delivery system for gastric photocoagulation is described. The system is usable with any conventional gastric or colonic fiberendoscope and can be readily inserted in the biopsy channel of an *in vivo* scope. The photocoagulator uses a water-cooled argon laser, along with a step-index cylindrical quartz-glass fiber-optical waveguide, and is capable of depositing in excess of 9 watts of continuous laser radiation at the site. The system was used to control experimentally produced gastric bleeding in 10 dogs, and acid-induced lesions of about 1 cm^2 were successfully controlled. The typical process of photocoagulation consisted of several 1 sec bursts of light of approximately 10 watts input laser power. With the aid of a synchronized filter to attenuate the laser radiation, the endoscopist can administer the pulses of light to the gastric mucosa while observing the progress of coagulation.

6415 THE EFFECT OF A PEPSIN-INHIBITION PENTAPEPTIDE ON THE SECRETION OF PEPSIN AND HYDROCHLORIC ACID IN THE STOMACH. (Dan.) Svendsen, L. B.; Guldager, N.; Christiansen, P. M. (Jenslovs Tvaervej 20, 4th, DK-2920 Charlottenlund, Denmark). *Ugeskr. Laeger* 137(39):2267-2269; 1975.

The effects of pepsin-inhibiting pentapeptide (PIP) on the production of pepsin and hydrochloric acid in the stomach were investigated in nine men with ulcers and high acid secretion. PIP (50 mg) was administered to 12-hr fasted patients. One hr later, the entire contents of the stomach were aspirated, and the patients were given 300 ml bouillon. The stomach contents were again aspirated, and PIP was repeated. Analyses of stomach fluid were taken every 15 min during this regimen. Control patients followed the same regimen, but were given placebo. Pepsin activity was found to be reduced by 72% within 15 min of ingestion of the drug, and by an additional 22% thereafter. After the meal, pepsin activity was reduced 100%, and remained at that level for at least an hour. For the controls, both administrations resulted in about a 36% reduction in pepsin activity within 15 min, and a subsequent return to normal levels. Stomach acidity was not significantly affected by the drug, which has no known side effects. These results confirm those previously reported from Japan. PIP should be further investigated to determine its clinical effect in ulcer disease.

6416 INTRAMURAL GASTRIC ABSCESS. (Eng.) Murphy, J. F.; Graham, D. Y.; Frankel, N. B.; Spjut, H. J. (Baylor Coll. Medicine, 1200 Moursund Ave., Houston, TX 77030). *Am. J. Surg.* 13(5):618-621; 1976.

Two cases of localized gastric abscess are described, and the pathologic findings are presented. A 59-yr-old man presented with an 11-month history of nausea and abdominal pain. For 2 months prior to hospitalization, he noted pain between the scapulae that could be brought on by lying supine for more than 6 hr and was immediately relieved when he sat up. The upper gastrointestinal series showed no abnormality. Exploratory laparotomy was performed, with the preoperative clinical diagnosis being possible pancreatic carcinoma. Two small nodules were found within the antral wall along the greater curvature. A 25% distal gastrectomy with gastroduodenostomy was performed, and the patient is asymptomatic 7 months after the procedure. A 57-yr-old woman presented with abdominal pain, fever, chills, and nausea. Cholecystitis was suspected. At surgery, a mass was noted in the stomach wall just proximal to the pylorus, and several large immediately adjacent lymph nodes were seen. Hemigastrectomy with gastroduodenostomy was performed, and the patient remains asymptomatic 5 months later. In both patients, the abscesses presented as elevated nodules. They were localized to the submucosa in both cases, and were associated with edema and acute inflammatory cells in the adjacent submucosa and muscularis propria. This was particularly notable in the second case. There was little organization around the abscess in either case. In the second patient, there was microscopic evidence of necrosis of part of the overlying mucosa.

6417 CONGENITAL PYLORIC ATRESIA: REPORT OF A FAMILIAR OCCURRENCE. (Eng.) Olsen, L.; Grotte, G. (Univ. Hosp., S-750 14 Uppsala 14, Sweden). *J. Pediatr. Surg.* 11(2):181-184; 1976.

An instance of familial pyloric atresia in two siblings is reported. The first child, a girl, was the first child of a healthy 26-yr-old woman, whose pregnancy was normal, apart from polyhydramnios. The Apgar score was 6 at 1 min after birth. The child had several aspirations during the first day of life and developed atelectasis and pulmonary infiltrations, shown on x-ray. Hyperbilirubinemia developed, and an exchange transfusion was performed. Atresia in the pyloric region was found at surgery, and a gastrojejunostomy was performed. Continued respiratory problems and circulatory failure resulted in death on the 23rd day of life. The second child, a boy, was born 1 yr later. Because the mother also had polyhydramnios, a pyloric atresia was immediately suspected and verified by x-ray. At surgery 1 day after birth, a membrane several millimeters thick was excised, and a gastroduodenostomy was performed. There were no complications, and the child is healthy at 19 months of age. Fifty-nine cases of congenital pyloric atresia have been reported. A familial occurrence has been described in 13 infants in six families.

6418 GASTRIC CANCER: SURVIVAL RATES WITH SPECIAL REFERENCE TO "EARLY GASTRIC CANCER." (Eng.) Kato, K.; Kito, T.; Nakazato, H.; Miyaishi, S.; Yamada, E. (Dept. Surgery, Aichi Cancer Center Hosp., Nagoya, Japan). *Nagoya J. Med. Sci.* 38(1/2):35-42; 1975.

The survival rates of 1,449 patients who underwent laparotomy for gastric cancer are reported, with particular emphasis on the effectiveness of curative gastrectomy. A total of 895 of these patients had a curative gastrectomy (either partial or total with removal of the second group lymph nodes, classified as NX+b). The 5-yr survival rate for these patients was 62.5%; the 5-yr survival for 267 of the 895 patients who had lesions classified as early gastric cancer (carcinoma involved the mucosa and/or submucosa but did not reach the muscularis propria) was 92.7%. Among four patients undergoing noncurative gastrectomy for early gastric cancer, no evidence of recurrence has been seen, despite the fact that these patients had tumor cells at the lines of resection as a result of inadequate resection. The reason for this is not clear, but early gastric cancer may behave in a more benign fashion than advanced gastric cancer. Overall it appears that gastrectomy with removal of the second group lymph nodes is adequate for the treatment of early gastric cancer.

6419 SURFACE CARCINOMA (EARLY CARCINOMA) OF THE STOMACH. (Ger.) Gloor, F. (Institut fur Pathologie, Kantonsspital, CH-9006 St. Gallen, Switzerland). *Schweiz. Med. Wochenschr.* 106(1):21-27; 1976.

Eighteen surface carcinomas were found among 284 histologically confirmed gastric carcinoma patients. There were 11 women and 7 men, 32-86 yr of age. The mass was confined to the mucosa in 16 cases and had infiltrated into the submucosa in 2. Staging included five type I, seven type IIc, four type III, and two types IIc and III. Localization was prepyloric in three, antral in six, at the angle in five, on the body in three, and in the cardia in one patient. The area of surface involvement was 1.0-2.0 cm^2 in seven cases, 2.1-5.0 cm^2 in seven, 5.1-6.0 cm^2 in two, and 12.0-16.0 cm^2 in two cases. Six were multicentric. The histology included six signet-ring carcinomas, three well-differentiated adenocarcinomas, five undifferentiated adenocarcinomas, and four mixed carcinomas. Nodal metastases were found in one patient whose primary tumor was a type IIc signet-ring mucosal carcinoma located at the angle. Small carcinomas occurred in two of seven with gastric node involvement. The preoperative diagnosis was established by endoscopic biopsy in 14 patients. Epigastric pain was the most frequent symptom, followed by gastrointestinal bleeding and weight loss. The literature of early gastric carcinoma diagnosis and prognosis is reviewed.

6420 RESULTS FROM THE TREATMENT OF GASTROINTESTINAL LYMPHORETICULOSARCOMAS: 16 CASES. (Fre.) Hollender, L. F.; Meyer, Ch.; Weill-Bousson, M.; Otteni, Fr. (Centre Hospitalier Universitaire, 67000 Strasbourg, France). *Med. Chir. Dig.* 3(5):337-346; 1974.

The epidemiology and histology of lymphoreticulosarcomas of the gastrointestinal system are reviewed together with data on 16 cases. The patients (3 women and 13 men) ranged in age from 33-74 yr (mean age, 52 yr). More than half (9/16) were stage I or II, i.e., the malignancy was localized and situated on one side of the diaphragm. Prognosis depends on the degree of dissemination and on the histology; patients with giant follicular types have a better chance of survival than those with undifferentiated lymphosarcomas. Rarely can the malignancy be diagnosed on the basis of clinical symptoms alone, and radiography is not always conclusive. Endoscopy can also give false results since the lesion is often submucosal. Treatment consists of surgery and radiotherapy since lymphosarcomas are particularly radiosensitive. Chemotherapy was used in addition to surgery in two cases. Survival of 2-3.5 yr was observed for three cases of stage I and II lymphosarcomas of the stomach. When the intestine was the site of the neoplasm, diagnosis was usually delayed until malignancy had evolved to stage III and only 1/7 survived for 2 yr; 2/7 deaths occurred postoperatively. The single case of lymphosarcoma of the colon, a stage II, survived 1 yr.

6421 RELATIONSHIP OF BILE IN THE STOMACH TO GASTRITIS. (Eng.) Goldner, F. H.; Boyce, H. W., Jr. (P.O. box 70652, William Beaumont Army Medical Center, El Paso, TX 79920). *Gastrointest. Endosc.* 22(4):197-199; 1976.

Studies were carried out in 50 patients undergoing gastroscopy for a variety of symptoms to determine whether there is a correlation between the fasting intragastric bile acid concentration and gastritis, the accuracy of the visual judgment of the amount of bile in the stomach, and the reliability of the endoscopic impression of gastritis. All but five patients had intact, nonoperated stomachs. The accuracy of the visual judgment of the amount of bile in the stomach was evaluated by plotting the degree of bile staining against the actual bile acid concentration. Moderate and heavy staining reliably reflected increasing bile acid concentrations ($p<0.01$). A bile acid concentration associated with mild staining was not statistically different from that found in the clear mucous lake ($p>0.05$). The endoscopic diagnosis of a normal stomach was confirmed by normal histology in only 21 of 54 cases. The remainder showed gastritis, sometimes of considerable degree. In contrast, in patients with an endoscopic diagnosis of gastritis, the biopsy confirmed the diagnosis in 28 of 32 cases. By plotting the degree of gastritis versus the bile acid concentration in the stomach, it was apparent that the degree of gastritis bears no relation to the fasting gastric bile acid concentration. Similarly, the postprandial bile acid concentrations in three patients undergoing hourly gastric aspirations for 24 consecutive hours were similar to those determined in specimens obtained from them during gastroscopy in the fasting state. The results suggest that the endoscopic diagnosis of mucosal normalcy should not be accepted without biopsy confirmation and that there may be factors more important than the presence of bile in the etiology of gastritis in patients in whom a bile-stained mucous lake is found.

6422 BILE REFLUX GASTRITIS. ANALYSIS OF FASTING AND POSTPRANDIAL GASTRIC ASPIRATES. (Eng.) Brooks, W. S.; Wenger, J.; Hersh, T. (Emory Univ. Clinic, 1365 Clifton Rd., N.E., Atlanta, GA 30322). *Am. J. Gastroenterol.* 64(4):286-291; 1975.

The pattern of the refluxed bile salt in 11 patients with bile reflux gastritis was investigated, and pH, bacterial cultures, and proteolytic activity were determined. Six patients had undergone Billroth II gastrojejunostomy, while the remaining five had had Billroth I anastomoses. The mean pH values for the two groups were similar: 6.49 ± 0.88 for fasting aspirates and 6.08 ± 0.85 for 2-hr postprandial specimens. The mean bacterial colony count was 1.76×10^7 colonies/cm^3 for the fasting specimens and 1.44×10^7 colonies/cm^3 for the postprandial specimens. The mean total proteolytic activity was 97 ± 59 U for fasting aspirates and 145 ± 61 U for the postprandial samples. An analysis of bile acids was completed on 14 specimens from 9 patients. Taurine and glycine conjugates were present, but with no predominance of either type. Conjugates of chenodeoxycholic acid were present in 13 specimens. Conjugates of deoxycholic acid were detected in 13, and conjugates of cholic acid were found in 12 specimens. Deoxycholic acid was the only free bile acid found in all fasting and postprandial samples. A new addition to the previously proposed pathophysiology of bile reflux gastritis is suggested. Peristomal gastritis may develop as a result of the reflux of duodenal and jejunal contents, leading to progressive loss of parietal cell function and parietal cell mass.

6423 EMOTION-RELATED GASTRITIS. (Eng.) Goldberg, S. J.; Smith, C. L.; Connell, A. M. (Dept. Internal Medicine, Univ. Cincinnati Coll. Medicine, Cincinnati, OH 45267). *Am. J. Gastroenterol.* 65(1):41-45; 1976.

The relation between emotional stress and abnormalities of the gastric mucosa was reviewed in 788 consecutive upper gastrointestinal endoscopies. In 24% of these examinations, either a focal or generalized gastritis was diagnosed. Among the 190 cases of gastritis, 82% appeared to have one or more specific factors or associated lesions predisposing to the abnormal mucosa: alcoholism (96 patients), salicylates (36), gastric ulcer (20), hiatal hernia (9), duodenal ulcer (6), nasogastric tube (9), gastroenterostomy or pyloroplasty (9), nonsalicylate ulcerogenic medication (7), or uremia, Zollinger-Ellison syndrome, chronic lung disease, cerebrovascular accident, pancreatitis, or sepsis (1 patient each). Of the 34 cases in which no contributing factor was evident, 53% had significant documented emotional problems: depression (6 patients), anxiety (5), depression plus anxiety (2), severe situational stress (1), personality disorder (1), chronic schizophrenia (2), and psychosomatic neurosis (1). The indications for endoscopy (dysphagia, abdominal pain, nausea or anorexia, chest pain, hematemesis or melena, abnormal upper gastrointestinal series, anemia or guaiac positive stool, and vomiting) were similar in both the emotion-related and non-emotion-related groups. The 53% incidence of emotional problems in the patients with otherwise unexplained gastritis was significantly greater than the incidence of 10% observed in 52 duodenal ulcer patients ($p<0.01$). The incidence was also significantly greater than the 25% incidence among 32 socioeconomically similar medical in-patients ($p<0.05$). The data support the hypothesis that emotional stress plays a role in altering the integrity of the gastric mucosa.

6424 ACUTE PYLORIC OBSTRUCTION BY GALLSTONE: REPORT OF A CASE DIAGNOSED BY GASTROSCOPY. (Eng.) Grove, O. (Hellerupvej 72, DK-2900 Hellerup, Denmark). *Gastrointest. Endosc.* 22(4): 212-213; 1976.

The case of a patient in whom the diagnosis of acute pyloric obstruction by a gallstone was made by gastroscopy is presented. The patient, a 64-yr-old man with a history of duodenal ulcer, presented with an 8-hr history of hematemesis preceded by stabbing pain in the epigastrium. There was occult blood in the stools. Immediate gastroscopy revealed a distended stomach containing several liters of hematin-colored liquid. The pylorus was open, with a diameter of about 1 cm. The stone could be seen through the opening. A preoperative barium meal showed the contours of an oval concrement located behind and below the pylorus. At surgery, a 4.2 x 2.8-cm gallstone located in the duodenal bulb with the pointed end occluding the pylorus was removed. There was a broad fistula from the duodenal bulb to a contracted gallbladder, but no additional stones and no signs of duodenal ulceration were seen. The patient did well postoperatively. This case illustrates that obstructions caused by gallstones or other foreign bodies may be precisely and rapidly diagnosed by endoscopy.

6425 CELLULASE BEZOAR INJECTION: A NEW ENDOSCOPIC TECHNIQUE. (Eng.) Gold, M. H., Jr.; Patteson, T. E., III.; Green, G. I. (Medical Coll. Virginia, Virginia Commonwealth Univ., Richmond, VA 23219). *Gastrointest. Endosc.* 22(4): 200-202; 1976.

Two cases of phytobezoar dissolution are presented that employed direct endoscopic injection of cellulase after failure of previously described nonsurgical techniques. The first patient, a 47-yr-old woman, presented with postprandial epigastric and left upper quadrant pain without vomiting. A 7 x 9-cm bezoar was discovered on the posterior wall of the body and fundus of the stomach by the upper gastrointestinal series and by gastroscopy. In addition, a contraction ring in the antrum was noted. The patient was instructed to ingest meat tenderizer and later, three tablets of cellulase. Each treatment failed to completely dissolve the bezoar, and symptoms persisted. Finally, six cellulase tablets were crushed and suspended in 300 ml of warm water. The suspension was injected directly into the body of the bezoar through a catheter inserted through the biopsy channel of the gastroscope. Upper gastrointestinal radiographs taken 2 weeks later revealed no evidence of the bezoar. The patient's symptoms persisted, due to antral stenosis proximal to the pyloroplasty done 2 yr earlier. The pyloroplasty was reconstructed as a long Heineke-Mikulicz procedure, and the patient has been asymptomatic for 4 months. The second patient, a 69-yr-old woman, presented with a 3-day history of epigastric pain, which was worsened by food and relieved by emesis. The patient had a previous vagotomy, hemigastrectomy, and Billroth I anastomosis. An 8 x 10-cm bezoar, discovered by gastrointestinal radiography and gastroscopy, was fixed to the gastric wall and extended from the proximal body of the stomach to just proximal to the anastomosis. Attempts to mechanically disrupt the mass with both the endoscope and biopsy forceps were only partially successful. Shortly after the procedure, the patient regurgitated several fragments of the bezoar. Further treatment with p.o. cellulase failed to dissolve the gastric remnant. Three days after cellulase was injected directly into the bezoar, the patient became asymptomatic, and upper gastrointestinal radiography 10 days later failed to demonstrate evidence of residual material. The authors believe that the described method of bezoar dissolution should be employed during the initial gastroscopy, and may obviate the need for hospitalization.

6426 BRUNNER GLAND HETEROTOPIA PRESENTING AS GASTRIC ANTRAL POLYPS. (Eng.) Johnson, C. D.; Bynum, T. E. (Methodist Hosp., Houston, TX). *Gastrointest. Endosc.* 22(4):210-211; 1976.

The rare case of a patient with Brunner's gland polyps (heterotopias) that produced symptoms of intermittent gastric outlet obstruction because of their size and location is presented. The patient, a 42-yr-old woman, presented with midepigastric pain of 2 week's duration, nausea, and vomiting. Gastroscopy revealed mild erythema with diffuse nodularity in the antrum. Two polyps were seen, the largest being juxtaposed to the pylorus, with a broad base attached to the lesser curvature. A third polyp was found in the duodenum, 1 cm distal to the apex of the duodenal bulb. These polyps were removed using the snare and electrocautery technique. The patient has experienced no recurrence of symptoms. Histologically, both gastric polyps showed hyperplasia of Brunner's glands beneath a normal gastric antral surface epithelium. This case is unusual because of the histology of the polyps and because these structures produced symptoms.

6427 THE ASSOCIATION OF DUODENOGASTRIC REFLUX WITH DUMPING AND GASTRIC RETENTION. (Eng.) Donovan, I. A.; Keighley, M. R. B.; Griffin, D. W.; Harding, L. K.; Alexander-Williams, J. (Dudley Road Hosp., Birmingham, England). *Br. J. Surg.* 63(5):349-351; 1976.

Because reflux of duodenal contents into the stomach may produce dumping and gastric retention after gastric operations, gastric emptying and duodenogastric reflux were studied in 20 patients before and after proximal gastric vagotomy (PVG, 9 patients) or truncal vagotomy and antrectomy (TV + A, 11 patients) for uncomplicated duodenal ulcer. Duodenogastric reflux was assessed either by a fluoroscopic technique or by determining whether the maximum bilirubin concentration obtained from four 10-min samples of fasting gastric juice was greater or less than 8-5 μM. Biochemical reflux (>8.5 μM bilirubin concentration) was present in eight subjects, seven of whom had radiological confirmation of pyloric regurgitation. Duodenogastric reflux occurred in seven patients with TV + A and in one patient with PGV ($p<0.05$). Delayed solid meal emptying occurred in eight patients with TV + A and in two patients with PGV ($p<0.05$). Cascading of liquids occurred in combination with delay in three patients with TV + A and in one patient with PGV. Cascading occurred in combination with reflux in one patient with TV + A delay and reflux in two patients, and cascading, delay, and reflux in three; none of these combinations were found in any patient who had undergone PGV. A clinical review of the patients was performed 3 months after surgery. Symptoms of dumping, gastric retention, and bile regurgitation or vomiting were then related to the abnormalities of motility. Of the seven patients with only one abnormality of motility, two had associated symptoms. However, 8 of the 10 patients with more than one abnormality had at least one associated set of symptoms. Therefore, there was a significantly greater risk of symptoms if more than one abnormality was present ($p<0.05$). The results confirm the impression that PGV is a desirable operation for peptic ulcer because of its relative freedom from side-effects associated with abnormalities of gastroduodenal motility.

6428 GASTRIC SARCOIDOSIS, PRESENTING AS ANTRAL SCARRING. (Eng.) Blackstone, M. O.; Dhar, G. J.; Mizuno, H.; Para, M. F. (Dept. Medicine, Univ. Chicago, Box 400, 950 East 59th St., Chicago, IL 60637). *Gastrointest. Endosc.* 22(4):211-212; 1976.

The case of a patient with gastric involvement in systemic sarcoidosis is presented. The patient, a 64-yr-old woman with a 5-yr history of sarcoidosis, presented with nonspecific gastrointestinal symptoms accompanied by a 65-pound weight loss. Over the preceding 4 months, she experienced a loss of salivation and tear formation. Upper gastrointestinal radiography showed irregularity and mild rigidity of the distal antrum. Fiberoptic gastroscopy revealed a somewhat thickened appearance of the antral folds, with an area in the prepyloric antrum of fold convergence and centeral depression suggesting an ulcer scar. Biopsy of these folds revealed noncaseating granulomas consistent with gastric sarcoidosis. The endoscopic finding of antral scarring indicated by converging folds should be added to the list of changes expected in gastric sarcoidosis.

6429 ULCER SIMULATING GASTRIC CARCINOMA: I. DIAGNOSTIC CONSIDERATIONS AND TREATMENT. (Eng.) Hakkiluoto, A.; Lempinen, M. (Univ. Central Hosp., 00290 Helsinki 29, Finland). *Ann. Chir. Gynaecol. Fenn.* 64(1):5-9; 1975.

Information concerning the diagnosis, radiological findings, gastroscopic findings, surgical treatment, and long-term mortality among 48 patients with small ulcer-stimulating carcinomas is presented. These 48 patients were among 1,324 patients treated for gastric carcinoma at one hospital between 1953 and 1971, an incidence of 3.9%. The mean age of the patients was 56.8 yr, and the male/female ratio was 31:17. Burning epigastric pain was the most important symptom. Eighteen patients had symptoms for less than 1 yr, 9 patients for 1-3 yr, and 21 patients for more than 3 yr. Thirteen patients were treated for "peptic ulcer" for 1-14 yr. Sixty percent of the patients were in blood group A. The x-ray findings suggested the diagnosis in 52% of 44 patients. Endoscopic examination was performed in 26 patients. In six cases, the lesion was thought to be a benign ulcer. In 13 patients, malignancy was suspected, and in 6 patients, a malignant ulcer was diagnosed by the gastroscopic findings. The ulcers were mostly in the distal part of the stomach, particularly on the lesser curve. In most patients, distal partial gastrectomy without splenectomy was performed. All patients were followed up for over 2 yr, and 38 patients were followed up for over 5 yr. Stomach carcinoma was the cause of death in 19 of 22 patients who died during the follow-up period. The survival time was 3 months to 10 yr. X-ray examination and gastroscopy in 13 patients revealed no recurrent carcinoma. However, gastric cytology revealed malignant cells in one patient who had undergone surgery 6 yr previously.

STOMACH

Peptic Ulcers

6478 HOSPITAL ADMISSIONS FOR PEPTIC ULCER DURING 1958-72. (Eng.) Brown, R. C.; Langman, M. J. S.; Lambert, P. M. (Ipswich Hosp., Ipswich, England). *Br. Med. J.* 1(6000):35-37; 1976.

Unpublished data on hospital discharges and deaths of patients with peptic ulcer in England, Wales, and Scotland between 1958 and 1972 was examined. During this time, admissions to hospitals in England and Wales of patients aged 15 yr or more with gastric and duodenal ulcers declined steadily, from 23,109 and 34,083 patients, resp., in 1958 to 11,918 and 29,988 patients, resp., in 1972. For both gastric ulceration and duodenal ulceration without perforation, the fall in admission rates per 100,000 population was similar for men and women. By contrast, admission rates for perforated ulcer fell more among men than among women, those for perforated gastric ulcer in men falling by over half. Among women, there was a small rise in the admission rate for perforated duodenal ulcer. There was a 14% and 19% decrease in nonperforated duodenal ulcer admissions in men and women, resp., during the periods 1958-1960 and 1970-1972. There were 44% and 34% decreases in nonperforated gastric ulcer in men and women, resp., during the same period and 56% and 14% decreases in perforated gastric ulcer in men and women, resp. There was a 25% decrease in perforated duodenal ulcer in men and a 12% increase in perforated duodenal ulcer in women. Admission rates for duodenal ulcer, both perforated and nonperforated, were consistently higher (approximately 3 times) in the north than in the south, and were highest in Scotland.

6479 GASTRIC EMPTYING IN CONTROL SUBJECTS AND PATIENTS WITH DUODENAL ULCER BEFORE AND AFTER VAGOTOMY. (Eng.) Howlett, P. J.; Sheiner, H. J.; Barber, D. C.; Ward, A. S.; Perez-Avila, C. A.; Duthie, H. L. (Sheffield Royal Infirmary, Sheffield, England). *Gut* 17(7):542-550; 1976.

Gastric emptying of a solid meal was studied in 26 normal subjects and in 27 patients with duodenal ulcers before and after surgery [truncal vagotomy and pyloroplasty (TV) or highly selective vagotomy (HSV)]. The patients were fed a meal of meat, peas, and mashed potatoes with a total weight of 250 g. Indium ^{113m}diethylene triamine pentaacetic acid (DPTA) was incorporated into the potatoes. The activity over the stomach was measured by gamma camera for 60 min from the beginning of the meal. The gastric emptying curve was analyzed by principle component analysis, half emptying time, and early emptying phase. With principal component analysis, the first coefficient showed no difference between the controls and patients before vagotomy. The second coefficient had a bimodal distribution in the ulcer group. The distributions of the two groups showed a significant difference ($p<0.01$). The second emptying coefficient showed a significant ($p<0.05$) correlation with peak gastric acidity in 15 patients who underwent secretory studies. The half-emptying time showed no difference in distribution or mean between the groups. Early emptying ratios showed no evidence of a fast initial phase, and the overall mean was significantly greater than 1.0 ($p<0.02$). After vagotomy, principal component analysis showed a significant delay ($p<0.001$) in emptying 1 week after either type of vagotomy in the first component. At 1 month, TV-patients were significantly slower ($p<0.05$) in gastric emptying than were preoperative or control subjects, while patients after HSV were not. These differences had disappeared by 6 months. The early emptying ratio results were identical to those found for the first component. At 6 months, the preoperative and HSV groups both had an initial phase of gastric emptying slower than the subsequent rate in each group. Six months after TV, the patients did not demonstrate this slower phase, the difference between the two operations being significant ($p<0.05$). A correlation with symptoms was made in a small group of 24 patients. There was a significantly greater incidence of episodic diarrhea after TV (six patients) than after HSV (one patient, $p<0.05$). A combined score for diarrhea and dumping showed a significant difference ($p<0.05$) between the TV and the HSV groups, with the majority of HSV patients being symptom-free. The third coefficient in principal component analysis distinguished 2 patients with moderate diarrhea from 12 who began recording 5 min after eating. In all 24 patients, the records started 25 min after eating showed no separation. Half emptying time showed no correlation with the overall symptom score or with any individual symptoms. Patients after TV had a significant correlation ($r=0.87$) between the initial emptying ratio and the combined score for dumping and diarrhea. HSV patients showed no correlation. It is concluded that principal component analysis is useful, because it does not demand preconceived concepts about the functional form of the data, but the usefulness of half-emptying time is questionable. The results show that by 6 months after surgery, the HSV patients were not significantly different from normal, while some of the TV patients still showed emptying abnormalities.

6480 GASTRIC EMPTYING OF A FLUID TEST MEAL IN HEALTHY VOLUNTEERS AND PATIENTS WITH DUODENAL ULCER BEFORE AND AFTER SELECTIVE PROXIMAL VAGOTOMY. (Eng.) Carlberger, G. (Serafimer Hosp., Stockholm, Sweden). *Scand. J. Gastroenterol.* 10(35): 45-47; 1975.

Gastric emptying of a fluid test meal was measured in seven healthy volunteers and in eight duodenal ulcer patients before and after selective proximal vagotomy. In the normal volunteers, there was a rapid emptying initially, but after 5 min, a slow emptying phase was seen. There was no significant difference in gastric emptying between the controls and the ulcer patients before operation. Among another group of eight duodenal ulcer patients who showed a complete lack of acid response to insulin following selective proximal vagotomy, the emptying curve showed a marked increase in both the initial and the slow phase. The author concludes that the rapid emptying may be caused by a defect in the ability of the stomach to relax, which may be due to the sectioning of the vagal fibers to the gastric corpus and fundus.

6481 EFFECT OF NORMAL AND ULCER-TYPE DIET ON THE ACIDITY OF GASTRIC CONTENTS IN PATIENTS WITH DUODENAL ULCER. (Eng.) de Paula Castro, L.; Filho, J. G.; Pessoa, W. (Hospital das Clinicas, UFMG, Belo Horizonte, Minas Gerais, Brazil). *Digestion* 13(4):241-245; 1975.

The value of using a bland versus a normal diet in the last stage of treatment for peptic ulcer was studied in 15 patients with uncomplicated duodenal ulcer. The bland diet included maizena, corn flour, porridge, milk, butter, grated cheese, rice, spaghetti, eggs, potato puree, and xuxu. The normal diet included milk, coffee, sugar, bread, butter, rice, beans, meat, spaghetti, green salad, cooked vegetable, oranges, banana, tomato, green bean pods, potato puree, rice, and sweetmeat. During the second week of maintenance on either a bland or normal diet, a nasogastric tube was inserted and left in for 3 days. The diets were distributed into five meals a day, and gastric juice was collected every half hour from 7:30 a.m. to 10 p.m. A graph of the mean pH level of the gastric contents of 10 patients given bland and normal diets revealed that there was no statistically significant difference between the two diets. The results demonstrate no therapeutic advantage to using a bland diet in treatment of ulcer patients.

6482 SERUM GASTRIN AND H$^+$ SECRETION AFTER VAGAL STIMULATION IN NORMAL SUBJECTS AND IN PATIENTS WITH DUODENAL ULCER. (Ger.) Kleybrink, H.; Fritsch, W.-P.; Rick, W.; Hausamen, T.-U. (I. Medizinische Universitatsklinik A, 4 Dusseldorf 1, Moorenstr. 5, W. Germany). *Med. Welt* 26(37):1540-1641; 1975.

The role of the vagus system in gastrin and HCl liberation in 5 healthy persons and 21 duodenal ulcer patients was examined using the hypoglycemia test. The success of the test depends on a reduction in blood sugar of at least 40 mg%, which was elicited by 0.2 U/kg of insulin. A significant

($p<0.001$) rise in gastrin from a mean of 58 pg/ml to a maximum of 138 pg/ml was established for healthy persons. For duodenal ulcer patients, the increase was from a mean of 61 pg/ml to 142 pg/ml ($p<0.001$). The areas under the gastrin curves (sum of pg/ml times 15 min) were not different in healthy persons and ulcer patients. HCl production in healthy persons rose from 1.2 mval/hr to 12 mval/hr ($p<0.005$) and in duodenal ulcer from 7.2 mval/hr to 36 mval/hr ($p<0.001$); the increase in the duodenal ulcer group was significantly higher than in healthy persons. The results show that the vagus liberates more HCl in duodenal ulcer patients than in healthy persons, an effect which is not a function of increased gastrin secretion. An increased activity of the vagus on target cells can be inferred. The mechanism is either by direct stimulation of HCl production or by elevating the cells' sensitivity to gastrin.

6483 THE EFFECT OF VAGOTOMY ANTRECTOMY OR VAGOTOMY PYLOROPLASTY ON THE RESPONSE OF THE ANTRUM TO MEAT EXTRACT IN DUODENAL ULCER PATIENTS.

(Eng.) Coutsoftides, T.; Himal, H. S. (Royal Victoria Hosp., 687 Pine Ave. West, Montreal, Quebec, Canada). *Ann. Surg.* 184(2):212-216; 1976.

Studies were carried out in 42 duodenal ulcer patients and 9 controls to determine whether there are two types of duodenal ulcer patients: those with normal acid output and those with elevated acid output. Basal gastric acid secretion was determined in fasted patients, as was bouillon- and betazole-stimulated acid secretion. The mean acid output in response to betazole (1-2 mg/kg, i.m.) in the duodenal ulcer patients (30.58 mEq/hr) was significantly greater than that of the controls (16.76 mEq/hr, $p<0.001$). All duodenal ulcer patients were grouped according to those who did or did not respond to bouillon (3 cubes in 150 cm^3 water, pH 7.0). Fourteen patients in whom food-stimulated basal output was at least twice that of basal acid output were labeled "antral responders," and the remaining patients were labeled "nonresponders." In the responders, the mean levels of bouillon-stimulated acid output (10.89 mEq/hr) and peak serum gastrin (105.04 pg/ml) were significantly increased over basal levels (3.23 mEq/hr and 67.71 pg/ml, resp., $p<0.05$). In four responders who were followed up 3 months following vagotomy and pyloroplasty, the mean bouillon-stimulated acid output level was decreased postoperatively (0.79 mEq/l) from the preoperative level (8.48 mEq/l, $p<0.05$), as was the postoperative betazole-stimulated output (4.06 mEq/l postoperatively, 21.41 mEq/l preoperatively, $p<0.05$). Twelve patients had vagotomy-antrectomy and Billroth II anastomosis. In the eight patients who responded to bouillon, vagotomy-antrectomy significantly decreased bouillon-stimulated output (0.57 mEq/l) and betazole-stimulated output (5.26 mEq/l) from preoperative levels of 8.68 and 26.72 mEq/l, resp. After vagotomy-pyloroplasty, in antral responders, peak and basal serum gastrin levels increased from mean preoperative values of 124.5 and 72.0 pg/ml, resp., to postoperative values of 197.0 and 192.0 pg/ml, resp. There was no difference between pre- and postoperative basal and peak gastrin levels in patients who did not respond to bouillon. Two patients had an incomplete vagotomy, indicated by a positive Hollander test: one after vagotomy-pyloroplasty and one after vagotomy-antrectomy. Antrectomy with an incomplete vagotomy abolished the bouillon-stimulated acid response. The results suggest that the bouillon-stimulation test can select patients with a significant antral component in whom vagotomy and antrectomy would be the appropriate procedure. The results also indicate that antrectomy will protect against recurrent ulceration in patients with incomplete vagotomy, and may explain the lower incidence of stomal ulceration in patients with vagotomy-antrectomy compared to vagotomy-pyloroplasty.

6484 THE BLEEDING MARGINAL ULCER: CATHETERIZATION DIAGNOSIS AND THERAPY.

(Eng.) Rosenbaum, A.; Siegelman, S. S.; Sprayregen, S. (Albert Einstein Coll. Medicine, Bronx, NY). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 125(4):812-815; 1975.

Five cases in which angiography was successfully employed in visualizing the bleeding site of marginal ulcers in the jejunum are reported. The patients ranged in age from 40 to 92 yr. They had undergone gastrojejunostomy for carcinoma of the head of the pancreas (1 case), partial gastrectomy and gastrojejunostomy for duodenal ulcer disease (3 cases), or subtotal gastrectomy and gastrojejunostomy for carcinoid tumor of the stomach (1 case), each between 7 months and 20 yr before the episode of bleeding. Emergency angiography with a selective superior mesenteric injection revealed the bleeding site in all cases. Pitressin infusion of the superior mesenteric artery was utilized in four cases, with permanent cessation of bleeding in two cases and transient control of bleeding in two cases. The favorable response of bleeding marginal ulcers to pitressin infusion is thought to be related to the tendency of the ulcers to be superficial, and thus, amenable to the induction of coagulation.

6485 GASTROCOLIC FISTULAE IN BENIGN PEPTIC ULCER DISEASE.

(Eng.) Kumar, G. K.; Razzaque, M. A.; Naidu, V. G.; Barbour, E. M. (Wayne State Univ. Sch. Medicine, 540 East Canfield Ave., Detroit, MI 48201). *Ann. Surg.* 184(2):236-240: 1976.

To call attention to the rare occurrence of gastrocolic fistula complicating nonsurgically-treated benign peptic ulcer disease, the cases of four patients with this condition are reported. The patients ranged in age from 12 to 51 yr. The presenting symptoms included abdominal pain in three patients, vomiting in one, fecal vomiting in one, diarrhea in one, bloody diarrhea in one, and weight loss in one. One patient had been taking aspirin every day for over 6 months. Another patient had been treated with ACTH for 4-5 weeks, and a third patient had taken aspirin and prednisolone for 3 yr. In all patients, the penetrating ulcer occurred in the greater curvature of the stomach. In one patient, the fistula occurred between the stomach, jejunum, and transverse colon. The fistula occurred between the stomach and the splenic flexure in one and between the stomach and the transverse colon in two. The fistula was visualized by a barium enema in three patients. In the remaining patient, in whom the fistula occurred between the stomach, jejunum, and transverse colon, the barium enema was normal, and the presence of the fistula was confirmed at laparotomy. The surgical procedure in this patient included subtotal gastrectomy with gastrojejunostomy and segmental resection of the transverse colon and part of the small bowel. In two of the remaining patients, partial or total gastrectomy, together with colectomy were performed. The last patient received a segmental colonic resection with hemigastrectomy and an end-to-end anastomosis of the colon. The authors believe that the incidence of this complication may rise significantly with the more common use of salicylates and corticosteroids.

6517 FIBEROPTIC ENDOSCOPY DURING LAPAROTOMY IN THE DIAGNOSIS OF SMALL INTESTINAL BLEEDING. (Eng.) Greenberg, G. R.; Phillips, M. J.; Tovee, E. B.; Jeejeeboy, K. N. (Dept. Medicine, Surgery, and Pathology, Univ. Toronto, Toronto, Ontario M5S 1A8, Canada). *Gastroenterology* 71(1):133-135; 1976.

The case of a 22-yr-old woman in whom the diagnosis of hereditary hemorrhagic telangiectasia was made by combining fiberoptic endoscopy and laparotomy is presented. The patient had a 4-yr history of recurrent melena and hematemesis, but barium studies, intestinal angiography, gastroduodenoscopy, sigmoidoscopy, and colonoscopy to the ileocecal valve were repeatedly normal. A laparotomy performed 3 months before hospitalization had not revealed the source of the blood loss. At the second laparotomy, the peritoneal cavity was entered through a right paramedian incision; several adhesions were taken down, and the duodenal-jejunal flexure was identified. The fiberoptic colonoscope was introduced p.o. and passed to the first part of the duodenum, where it could be pulled into the proximal jejunum. By extending the small bowel over the distal 40 cm of the colonoscope in concertina-like fashion, the entire small intestine was visualized. Approximately 18-20 red raised lesions, consistent with telangiectasia, were observed in the proximal 55 cm of jejunum. The involved segment was resected. The same procedure was performed 1 month later, when bleeding recurred; 60 cm of jejunum containing new lesions was resected. The procedure was performed a third time, when new lesions in the remaining jejunum and the third part of the duodenum were found. A Whipple's procedure with duodenoileal anastomosis was performed, and the patient has remained asymptomatic for 6 months. Although the endoscopy-laparotomy combined procedure should be reserved for the most difficult diagnostic problems, the use of this technique may permit complete visualization of the entire gastrointestinal tract, and enhance the clinician's ability to identify small intestinal bleeding sources that previously have gone unrecognized.

6518 SUCCESSFUL REPAIR OF A PRIMARY AORTODUODENAL FISTULA. (Eng.) Brenowitz, J. B.; Williams, C. D. (4300 Brand, NE, Albuquerque, NM 87109). *Am. Surg.* 42(4):265-267; 1976.

The case of a 79-yr-old man who underwent successful repair of a primary aortoduodenal fistula is presented. The patient presented with a 1-day history of weakness and melena. There was no abdominal mass, and the patient denied back pain. He passed large amounts of blood per rectum on two occasions, and both times, his blood pressure was restored with whole blood transfusions. The nasogastric aspirate was positive for whole blood. Laparotomy revealed an 8-cm aneurysm of the infrarenal aorta, adherent to the posterior wall of the third part of the duodenum, and an aortoduodenal fistula with a 1.5-cm opening into the duodenum. The duodenal wall was repaired in two layers using No. 000 polypropylene suture. The aneurysm was then resected, and the aorta was replaced with a 19 x 9.5-mm woven dacron bifurcation graft using systemic heparinization. The suture lines were separated with aneurysm wall, peritoneum, and greater omentum to prevent secondary fistulization. Postoperatively, the patient was treated for mild congestive heart failure. He was discharged on the 16th hospital day and has continued to do well for 6 months.

6519 EFFECT OF SMALL BOWEL BYPASS ON SERUM GASTRIN LEVELS AND GASTRIC ACID SECRETION IN MAN. (Eng.) Solhaug, J. H.; Schrumpf, E. (Haukeland Hosp., 5000 Bergen, Norway). *Scand. J. Gastroenterol.* 11(3):329-332; 1976.

The question of whether hypersecretion of serum gastrin or gastric acid occurs in man after intestinal resection was investigated in six patients in whom 20 cm of proximal jejunum was anastomosed to the distal 25 cm of ileum in a jejunoileal bypass operation. The mean basal gastric volume and acid secretion rate at 6 months and 1 yr (46 ml/30 min and 2.57 mEq/30 min, resp., at 6 months; 38 ml/30 min and 1.96 mEq/30 min, resp., at 1 yr) were significantly higher than preoperative values (22 ml/30 min and 0.68 mEq/30 min, resp.). No significant differences were found in pentagastrin (6 μg, s.c.)-stimulated volume or acid secretion. The fasting concentration of serum gastrin at 6 months (mean, 37 pg/ml; $p<0.02$) and 1 yr (mean, 47 pg/ml; $p<0.02$) after operation was significantly increased in comparison with preoperative levels (mean, 25 pg/ml). Whether the increase in basal secretion and serum gastrin concentration is interrelated or of any clinical importance is uncertain.

6520 GASTRIC EMPTYING AND BILE ACID CONCENTRATION IN THE DUODENUM AFTER BYPASS OPERATION OF THE SMALL INTESTINE BECAUSE OF OBESITY. (Eng.) Moberg, S.; Carlberger, G. (St. Goran's Hosp., Box 12500, S-112 81 Stockholm, Sweden). *Scand. J. Gastroenterol.* 11(2):151-154; 1976.

Gastric emptying was measured concomitantly with bile acid concentration in the duodenum of nine patients who had undergone jejunoileal bypass. The results of the gastric emptying experiments were compared with those from seven healthy volunteers. In the seven bypassed patients who had not also undergone cholecystectomy, there was a sharp rise in bile acid concentration to a peak value between 5 and 17 min. Thereafter, the values dropped and leveled off at 4-13 mM. In the two cholecystectomized patients, no peak in bile acid concentration occurred during the first 20 min; the values were between 3 and 11 mM. The gastric emptying rate was within normal limits, except in one cholecystectomized, shunt-operated patient who had an extremely low bile acid concentration; there was a constant fall from approximately 5 mM at 3 min to approximately 1 mM at 30 min. It is concluded that the upper part of the small intestine functions well in shunt-operated patients if the gallbladder and at least 10 cm of the distal ileum are left intact.

6521 THE PATHOGENESIS OF DIARRHEA AFTER BYPASS OF THE SMALL INTESTINE. (Eng.) Wise, L.; Stein, T. (New Hyde Park, NY). *Surg. Gynecol. Obstet.* 142(5):686-688; 1976.

The relative importance of bile and fatty acids in the etiology of diarrhea following small intestinal bypass was evaluated in 29 patients. Seven patients were studied before the operation, 8 were studied in the early postoperative period (<2 weeks after operation), and 14 composed the late postoperative group (6-24 months after the operation). The mean fecal weight in the preoperative group was 421 g/48 hr, which increased significantly during the early postoperative period (2,006 g/48 hr) and the late postoperative period (1,155 g/48 hr). The fecal bile salt output in the late postoperative group (1.6 g/48 hr) was increased significantly over that in the preoperative group (0.6 g/48 hr). The free fatty acid output in the postoperative group (12.5 g/48 hr) was also increased over that in the preoperative group (2.2 g/48 hr). There was a significant Spearman correlation ($p<0.05$) between bile salt output and stool weight in both the early and late postoperative groups. There was no significant correlation between fecal weight and fecal fatty acid output. This suggests that after small intestinal bypass bile salts play a more significant role in the pathogenesis of diarrhea than do free fatty acids.

6522 INTUSSUSCEPTION FOLLOWING JEJUNOILEAL BYPASS: CASE REPORT AND REVIEW OF THE LITERATURE. (Eng.) Wise, L.; Boucher, J. K.; Feutz, E. (Long Island Jewish-Hillside Medical Center, New Hyde Park, NY 11040). *Am. Surg.* 42(5): 346-349; 1976.

The case of a 40-yr-old man who developed intussusception 11 months following a jejunoileal bypass operation is presented. The patient experienced colicky pain 10 months after the operation, but was otherwise asymptomatic. Despite the disappearance of the pain, the patient's hemoglobin decreased, which was accompanied by persistent guaiac-positive stools. Subsequently, he developed tarry stools, a further drop in hematocrit, and massive gastrointestinal hemorrhage, expelling fresh blood per rectum. During the active blood loss, an emergency selective superior mesenteric arteriogram revealed marked extravasation of contrast from a branch of the superior mesenteric artery supplying the jejunum. The venous phase further helped to localize the bleeding site to the jejunum by showing puddling of contrast material between the valvulae conniventes of a dilated segment of small intestine. Inspection of the excluded intestinal segment at laparotomy revealed that the most proximal segment of jejunum had intussuscepted. The intussusception was irreducible, so it was resected. The remaining stump was oversewn and then sutured to its mesentery. The patient made an uneventful recovery. The authors found only 12 previous reports of intussusception among 722 well-documented cases.

6523 DUODENAL CONTRACTION WAVE PATTERNS IN PATIENTS WITH AND WITHOUT ULCER. (Eng.) Monto, G. L.; Ashworth, W. D.; Malecki, M.; Thompson, A. B.; Englert, E. (Veterans Admin. Hosp., 2200 Gage Blvd., Topeka, KS 66622). *Am. J. Gastroenterol.* 65(1):52-56; 1976.

Attempts were made to compare the relative frequencies of isolated, simultaneous, peristaltic, and mixing waves in 10 patients with duodenal ulcers and in 14 control patients without ulcer. A water-perfused tube system was used. The frequency of waves in the proximal duodenum was decreased, and the frequency of waves in the distal duodenum was increased in ulcer subjects as compared to controls. This involved a statistically significant decrease in numbers of mixing (or basic rhythm) waves in the proximal duodenum. Increased numbers of isolated waves were found in ulcer patients in the distal duodenum. The predominant types of contraction waves in both ulcer and control subjects were isolated, and simultaneous waves, with peristaltic waves, were less common in the fasting state. These findings suggest that differences exist in the types of contraction waves in duodenal ulcer subjects compared to controls.

6524 QUANTITATION OF INTESTINAL-TISSUE LAYERS FROM THEIR HISTOLOGY. (Eng.) Younoszai, M. K.; Ranshaw, J. C. (Univ. Hosp. Clinics, Univ. Iowa, Iowa City, IA 52242). *Am. J. Dig. Dis.* 20(8): 764-770; 1975.

A line-sampling technique was used to quantitate the relative proportions of tissue components in p.o.-obtained small intestinal mucosal biopsies. The validity of the technique was tested in six male and six female Holzman rats, in which there is a sex difference between the intestinal size. In 10 specimens from healthy human subjects, the villus epithelium formed 41-46%, the crypt epithelium 20-26%, and the lamina propria 34% of the mucosa. In 10 specimens from patients with gluten enteropathy, the villus epithelium formed 7%, crypt epithelium 43%, and lamina propria 50% of the mucosa. In nine individuals with chronic diarrhea with malabsorption, the percentages of the tissue components were intermediate between those of healthy individuals and those with gluten enteropathy (27%, 30%, and 43% villus epithelium, crypt epithelium, and lamina propria, resp.). In adjacent segments of intestine from rats, the actual weight of the scraped mucosa and that of the underlying tissues correlated very well with their corresponding weights estimated from the microscopic histology, using the line-sampling technique. The intestinal tissue layers quantitated were the villus epithelium, crypt epithelium, the lamina propria plus muscularis mucosae plus submucosa, and the muscle plus the serosal coats. This study shows that the line-sampling technique can be used to estimate volume of the epithelial and nonepithelial tissues in the intestinal wall.

6525 ORAL TREATMENT OF ACRODERMATITIS ENTEROPATHICA WITH ZINC SULFATE.

(Eng.) Der Kaloustian, V. M.; Musallam, S. S.; Sanjad, S. A.; Murib, A.; Hammad, W. D.; Idriss, Z. H. (Dept. Pediatrics, American Univ., Beirut, Lebanon). *Am. J. Dis. Child.* 130(4):421-423; 1976.

The case of a 7-yr-old boy who was successfully treated with p.o. zinc sulfate for acrodermatitis enteropathica is presented. The child had been breast fed until the age of 7 months, when cow's milk was substituted. At that time, alopecia, diarrhea, and skin lesions developed. The diagnosis was made at the age of 1 yr, and treatment with diiodohydroxyquin (325 mg/day, p.o.) was begun. He was successfully treated with this drug until the age of 4 yr, when iodochlorhydroxyquin (500 mg/day, p.o.) was substituted. This treatment was discontinued when the patient was 7 yr old, because of decreased vision. At this time, he was apathetic and weak, and lesions and diarrhea recurred. His hair was sparse and of a woolly consistency. Within 48 hr of the start of zinc sulfate treatment (50 mg 3 times daily, p.o.), there was a definite improvement in the skin lesions, and the diarrhea stopped. At 61 days after the onset of zinc sulfate therapy, the serum zinc level was 160 µg/100 ml; the patient's lesions had healed completely, and healthy hair had started to grow. Zinc sulfate is an innocuous, inexpensive, and effective medication for acrodermatitis enteropathica and can replace the toxic diiodohydroxyquin-like drugs.

6526 FUNCTIONAL AND HISTOLOGICAL STUDY OF THE SMALL INTESTINE IN CHRONIC ALCOHOLISM.

(Fre.) Dedieu, P.; Mussini, J.; McOudea; Miniconi, P. (Clinique Medicale Propedeutique et des Maladies de l'Appareil Digestif, C.H.U. de Nantes, F 44035 Nantes Cedex, France). *Arch. Fr. Mal. App. Dig.* 64(8):639-651; 1975.

Absorption disorders and small intestinal mucosal alterations were studied in 20 chronically alcoholic, but not cirrhotic, patients. Four patients had no evidence of malabsorption. Results of test doses administered to patients indicated malabsorption in 55% after 50 g lactose, 10% after 50 g glucose, 45% after 25 g xylose, 20% after 80 g/day lipids, and 20% after vitamin B_{12} (Schilling test). Lesions of the intestinal mucosa were few and discrete, and thus cannot explain the malabsorption phenomena observed. Ultrastructural alterations of enterocytes were nonspecific and did not affect the microvilli. Intestinal motility studied by barium transit was normal. Intraluminal factors could be implicated in a few patients, suggesting that the malabsorption is an essentially functional alteration and not a morphological anomaly of the enterocytes. The possible role of the folic acid deficit, often associated with chronic alcoholism, in the absorption disorders is discussed.

6527 INTRAMURAL HEMATOMA OF THE DUODENUM.

(Eng.) Prathikanti, V.; Bhuta, I. (Goodrich Medical Center, PC. 7320 S. State Rd., Goodrich, MI 48438). *South. Med. J.* 69(4):490-492; 1976.

The case of a 44-yr-old man with an intramural hematoma of the duodenum is presented, together with a literature review. The patient was hospitalized with a 2-week history of upper abdominal, crampy pain and anorexia associated with vomitus without bile. He had had obstipation for 4 or 5 days. Physical examination revealed a dry tongue and an epigastric mass 3 inches in diameter, situated midway between the xiphisternum and the umbilicus. A routine film of the abdomen revealed a fluid-filled stomach, capped by an air fluid level. A barium enema examination revealed downward displacement of the hepatic flexure and of the proximal portion of the transverse colon. The upper gastrointestinal series revealed pyloric obstruction, which was confirmed at gastroscopy. An exploratory laparotomy revealed a hematoma measuring 3 x 3 x 3 inches, situated over the anterior wall of the duodenum, and extending from the pylorus to the commencement of the second portion of the duodenum. The hepatoduodenal ligament was thick, edematous, and hemorrhagic, and the head of the pancreas was slightly edematous. A longitudinal incision was made over the duodenal serosa, and the hematoma was evacuated. The proximal jejunum was brought in in an anticolic fashion, and a full-thickness jejunal-serosal patch was applied, using 000 interrupted silk sutures. Gastrostomy was performed for decompression of the stomach. The patient made an uneventful recovery. An intramural hematoma usually occurs after blunt trauma, although this was not reported by the patient.

6528 CHANGING CONCEPTS OF DUODENITIS.

(Eng.) Gelzayd, E. A.; Biederman, M. A.; Gelfand, D. W. (23077 Greenfield Rd., Suite 250, Southfield, MI 48075). *Am. J. Gastroenterol.* 64(3):213-216; 1975.

The results of ongoing studies of the clinical, radiographic, endoscopic, and pathologic changes in nonspecific duodenitis are reported. A total of 42 fiberduodenoscopic examinations were performed on 40 patients with this syndrome. Dyspeptic epigastric distress was the most common symptom, and occurred in 30 patients. Melena and/or hematemesis occurred in 14 patients and was usually associated with the erosive form of duodenitis. Peptic ulcer-like symptoms occurred in only 8 of the 38 patients who experienced epigastric distress. Radiographically, 11 patients had a normal duodenal bulb. Duodenal bulb spasm, seen in 18 patients, was the most common abnormality. Six patients had thick or nodular folds. The endoscopic findings fell into two categories: mucosal nodularity and erythema (28 patients) and erosions and friability (14 patients). Pathologically, increased inflammatory cell infiltration of the lamina propria and sometimes of the Brunner's gland area was observed in all patients. The infiltrate was composed of polymorphonuclear neutrophils, eosinophils, and mononuclear cells. Twenty-four patients had superficial mucosal erosions of the surface epithelial layer, and 12 patients showed villous changes with crypt dilatation. Of 26 patients who underwent repeat duodenoscopy and biopsy over a 3-yr follow-up period, there was a decrease in nodularity and erythema in 13 of 18 and a decrease in erosions and friability in 2 of 8 patients. A vigorous ulcer regimen was used for the erosive form of duodenitis, whereas anticholinergic-sedative drugs were used in the patients with the nodular-erythematous form of disease. Nodularity and erythema was increased in one patient, and no change was observed in four. Erosions and friability did not change in two patients and completely disappeared in four. Most patients responded initially to anticholinergic, tranquilizer, or antacid therapy. However, clinical correlations with long-term treatment will require controlled studies.

6529 ANGIOGRAPHY IN ACUTE ISCHEMIA OF THE SMALL INTESTINE. (Ger.) Voegeli, E.; Binswanger, R. (Institut fur Diagnostische Radiologie, Inselspital, CH-3010 Bern, Switzerland). *Schweiz. Med. Wochenschr.* 105(39):1258-1263; 1975.

The value of visceral angiography (VA) complementary to clinical and radiological diagnosis of acute small bowel ischemia was studied retrospectively in 17 patients. Selective presentation of the superior mesenteric artery (SMA) was performed in 14 cases, and abdominal aortography in 3, all of which preceded conventional radiology. All results were confirmed preoperatively or at autopsy. Two patients had well-defined ileus, and 15 had primary disturbances in vascularization. SMA occlusion was found in nine, but not in three cases with peripheral segmental ischemia, including one with aortic aneurysm. Three patients showed VA signs of functional angiospastic mesenteric deficit, with delayed contrast media transit through the mesenteric arteries; all three succumbed in 24-48 hr to extensive infarction of the small bowel and colon. No evidence of vessel occlusion was found at autopsy. In both ileus cases, the VA finding was characterized by partly stenosed and occluded mesenteric arterial branches. VA conveys the exact topographical localization of vascular occlusion and defines the extent of functional angiospastic mesenteric insufficiency. Visceral angiography can play a decisive role in the selection of therapeutic options.

6530 MIDGUT MALROTATION PRESENTING IN ADULT LIFE. (Eng.) Freund, H.; Schiller, M.; Eyal, Z. (Hadassah Univ. Hosp., Jerusalem, Israel). *Chir. Gastroenterol.* 9(3):399-402; 1975.

Two unusual cases of midgut malrotation discovered in adults are presented. The first patient, a 13-yr-old boy, presented with a 3-month history of severe crampy abdominal pain and vomiting. The midgut malrotation was observed in the upper gastrointestinal series and barium enema examination. At laparotomy, the whole bowel from duodenum to the descending colon was found to be suspended from a single narrow dorsal mesentery based on the origin of the superior mesenteric vessels. The ileum entered the cecum from the right. The second patient, a 25-yr-old man, presented with an 8-month history of crampy abdominal pain and vomiting. The upper gastrointestinal series revealed a deformed duodenal bulb, and barium enema showed the large bowel to be in the left abdomen. A misdiagnosis of duodenal ulcer causing pyloric stenosis was made, but at laparotomy the malrotation was found. The duodenum was unrotated and twisted back on itself, and the small bowel had a long mesentery. The ileum entered the cecum from the right. In both patients, fibrous bands were found crossing the abdominal cavity. In both cases, the bands were divided, the intestine was sutured to the posterior abdominal wall, and appendectomy was performed.

6531 A NEW COMPLEX METHOD OF DIAGNOSIS OF INTESTINAL DISEASES. (Rus.) Masevich, T. G.; Kudryashova, G. P.; Ugolev, A. M. (Leningrad Inst. Hygiene and Medicine, Leningrad, USSR). *Ter. Arkh.* 48(3):96-103; 1976.

6568 CLINICAL CYTOLOGICAL INVESTIGATIONS OF THE RECTUM AND DISTAL COLON. (Ger.)
Miczban, I.; Feher, M.; Gallyas, K. (Janos Korhaz, 1122 Budapest XII, Maros u. 38 II IZ, Hungary). *Tijdschr. Gastroenterol.* 18(3):161-170; 1975.

The role of cytological assay in the diagnosis of rectosigmoid pathology is explored. Mucosal specimens from 305 patients were obtained by an abrasion technique 0-30 cm from the anal ring during rectoscopy. Three types of cells were identified. One type consisted of columnar epithelial cells. A second type featured a round shape, cytoplasmic vacuoles and inclusions, and frequently a pyknotic nucleus ("Kolika" cells). The third type involved reticuloendothelial cells, including eosinophils, histiocytes, and plasma cells. Three main types of cytogram (CGM) originated from mixtures of the three cell types. The first CGM was cell-poor and included all three cell types. The second CGM was cell-rich; each of its three subtypes was dominated by one of the three cell types. The third CGM was characterized by heavy exfoliation, and probably consists of epithelial fragments. The role of this taxonomy in differential diagnosis is discussed.

6569 DIAGNOSTIC COLONOSCOPY. AN ASSESSMENT OF THE CLINICAL INDICATIONS. (Eng.) Schmitt, M. G., Jr.; Wu, W. C.; Geenen, J. E.; Hogan, W. J. (Rockford Clinic, Ltd., 2300 North Rockton Ave., Rockford, IL 61101). *Gastroenterology* 69(3):765-769; 1975.

Experience with 276 consecutive diagnostic colonoscopic examinations was analyzed to determine the specific clinical situations in which colonoscopy is beneficial in the diagnosis or management of colon diseases. Colonoscopy was successful in 260 patients. Using colonoscopy and biopsy, the location and type of colon disease was determined in 110 of 141 patients who had an abnormality on a colon x-ray examination. Of 43 patients with chronic inflammatory bowel disease, 31 were found to have more extensive colon involvement than had been indicated by a barium enema examination performed within 3 weeks before colonoscopy. In 13 patients with rectal polyps, colonoscopy revealed that 2 had polyps in the descending colon; this had not been demonstrated by proctoscopy or barium enema. Six cases of colonic polyps, one case of postirradiation colitis, two cases of blood within a colonic diverticulum, and one case of colonic carcinoma were diagnosed by colonoscopy. All of these patients were included in a group of 22 patients with chronic gastrointestinal bleeding who had normal x-ray examinations of the esophagus, stomach, and colon, as well as normal esophagogastroduodenoscopy. Nine patients who had a normal upper gastrointestinal endoscopic examination were colonoscoped for suspected acute lower gastrointestinal bleeding; in only two cases was the bleeding site (a solitary splenic flexure ulcer and a segmental inflammatory lesion, resp.) revealed by the procedure. Colonoscopy with biopsy demonstrated recurrent tumor in 2 of 13 postcolon surgery patients who had a colonic mucosal lesion described on a follow-up barium x-ray examination. No mucosal abnormality was detected by colonoscopy in six patients with chronic abdominal pain. Among nine patients with miscellaneous indications for colonoscopy, the procedure was beneficial in the evaluation of colonic endometriosis (3 patients) and rectal strictures (2) and in decompressing two patients with idiopathic pneumomegacolon. It is concluded that colonoscopy is indicated in patients with abnormalities on barium x-ray, chronic gastrointestinal bleeding, barium x-ray abnormalities that appear following colonic surgery, and selected patients with chronic inflammatory bowel disease.

6570 DISTAL COLOMYOTOMY: FOLLOW-UP OF 37 CASES. (Eng.) McGinn, F. P. (Southampton Univ. Medical Sch., Southampton, England). *Br. J. Surg.* 63(4):309-312; 1976.

The early postoperative results in 37 patients who underwent distal colomyotomy were evaluated, together with the 3- to 7-yr follow-up results of the 32 surviving patients. In each case, a longitudinal myotomy was made along the antimesenteric border of the sigmoid colon proximal to the level of the pelvic peritoneal reflection. In all cases, the myotomy was at least 25 cm long. The colon was perforated during surgery in seven patients. Wound abscess occurred in five patients, pelvic abscess in one, and wound dehiscence in one. There were two deaths following surgery. The first was a 76-yr-old man with widespread fecal peritonitis whose perforation was closed. The second death was a 68-yr-old woman who had had a previous transverse colostomy and drainage of a pericolic abscess; she died from a myocardial infarction and acute left ventricular failure. Most patients were discharged from the hospital within 14 days of admission. Three patients were discharged longer than 28 days after admission, and the reasons for this were a large wound abscess in two and a pelvic abscess in one. Among the 25 patients undergoing myotomy for uncomplicated diverticular disease and/or spastic colon, all were alive at the 3- to 7-yr followup, and 14 were asymptomatic. Of the six patients in this group operated on for spastic colon without any definite radiological evidence of diverticular disease, four were asymptomatic. Five of 10 patients who underwent surgery for complicated diverticular disease were asymptomatic; three of the remainder had persisting pain and two had died of unrelated diseases. Only 5 of 21 patients who agreed to have a barium enema examination showed any improvement at followup. The results of this operation for uncomplicated diverticular disease gave results comparable with, but no better than, optimum results after resection in other series. The results of myotomy for complicated diverticular disease were not as good as those obtained in recent studies with alternative forms of surgery.

6571 PLAIN FILM DIAGNOSIS OF RETROCECAL APPENDICITIS. (Eng.) Vaudagna, J. S.; McCort, J. J. (Santa Clara Valley Medical Center, 751 South Bascom Ave., San Jose, CA 95128). *Radiology* 117 (3):533-536; 1975.

The plain radiographic findings in 21 patients with acute retrocecal appendicitis were analyzed. In two patients, the appendix was completely retroperitoneal, and in the others, it was retrocecal with a partial or complete peritoneal covering. In all but three patients, the abdomen was examined in three projections: supine, left lateral decubitus with horizontal beam and anteroposterior upright. In order of frequency, the changes that suggested retrocecal appendicitis were: edema infiltration of the properitoneal fat between the ileac crest and the costal margin (11 patients), soft-tissue density interposed between the lateral fat line and ascending colon (9), a coprolith above the level of the anterior superior or ileac spine (7), gas in the appendix above the iliac crest (3), haustral irregularity of the lateral margin of the ascending colon (2), and retrocecal, extraperitoneal gas (1).

6572 RETROCECAL APPENDICITIS PRESENTING WITH AIR IN THE SUBHEPATIC SPACE.

(Eng.) Harned, R. K. (Univ. Nebraska Medical Center, Omaha, NB). *Am. J. Roentgenol.* 126(2):416-418; 1976.

Two cases in which the presence of subhepatic air played a decisive role in the diagnosis of clinically unsuspected appendicitis are reported. In the first patient, a 13-yr-old boy presenting with midabdominal pain and vomiting, air in a subhepatic abscess was the only abnormal plain roentgenographic finding. A barium enema was the initial contrast examination because of the patient's negative history for duodenal ulcer. In the second patient, a 66-yr-old man with a history of perforated duodenal ulcer, a barium meal examination was performed to exclude a diagnosis of recurrent perforation. The abdominal roentgenogram showed air in a subhepatic abscess, as well as evidence of abscess formation in the right paracolic gutter. In both cases, the free air on the supine abdominal roentgenogram assumed an oval configuration. Only the tip of the retrocecal appendix perforated distally into the subhepatic space, with resulting abscess formation and subsequent retrograde involvement of the right paracolic gutter by inflammatory exudate. Irritability of the right colon, present in both patients, was most likely secondary to this exudate. If the radiologist considers appendiceal disease when he finds air in the right subhepatic space, the patient may be spared unnecessary diagnostic procedures.

6573 SYNCHRONOUS ADENOCARCINOMA OF THE VERMIFORM APPENDIX AND THE RECTOSIGMOID: CASE REPORT AND REVIEW OF THE LITERATURE.

(Eng.) Birla, R. K.; Nolan, R. B.; Birla, S. R. (Beekman Downtown Hosp., 655 Park Ave., New York, NY 10021). *Dis. Colon Rectum* 18(8):678-684; 1975.

The unusual case of a patient with an adenocarcinoma of the appendix occurring simultaneously with a carcinoma of the rectosigmoid is presented. The patient, a 67-yr-old man, presented with a 24-hr history of right lower quadrant pain. A vague mass was found in this area. A meglucamine diatrizoate enema examination revealed an annular filling defect in the rectosigmoid suggestive of carcinoma and an irregularity at the tip of the cecum. Proctosigmoidoscopy revealed an ulcerating mucosal lesion with everted edges on the anterior wall, 18 cm from the anal verge. At exploratory celiotomy, one mass in the distal sigmoid and one in the area of the cecum and appendix were found. Metastatic adenocarcinoma was found in one of the four mesenteric nodes adjacent to the right colic vessels and in 7 of the 16 lymph nodes beside the inferior mesenteric vessels. A subtotal colectomy, with ileorectal anastomosis below the level of the peritoneal reflection, and a segmental resection of ileum adherent to the appendiceal mass were performed. The inferior mesenteric, right colic, and middle colic vessels were ligated at their respective origins, thus ensuring complete removal of the regional lymphatic drainage. A literature search failed to reveal another similar case.

6574 5-FLUOROURACIL (NSC-19893), DTIC (NSC-45388), BCNU (NSC-409962), AND VINCRISTINE (NSC-67574) IN AOVANCED COLORECTAL CARCINOMA.

(Eng.) von Eyben, F. E.; Larsen, V.; Pedersen, H. (Dept. Surgery, Finseninstitutet, Strandboulevarden 49, DK-2100 Copenhagen, Denmark). *Cancer Treat. Rev.* 60(1):29-32; 1976.

Combined therapy with 5-fluorouracil (5-FU), 5(3,3-dimethyl-1-triazeno)imidazole-4-carboxamide (DTIC), 1,3-bis(2-chloroethyl)-1-nitrosourea (BCNU), and vincristine for advanced colorectal carcinoma was evaluated in 33 patients. The patients received 5-day courses of 5-FU (10 mg/kg/day, i.v., days 1-5), DTIC (3 mg/kg/day, i.v., days 1 and 2), BCNU (1.5 mg/kg/day, i.v., day 1 only), and vincristine (0.025 mg/kg/day, i.v., day 1 only) at 5-week intervals. One patient achieved complete recovery (disappearance of tumor lesions and cancer symptoms), and six patients achieved partial recovery (at least 50% regression of a representative tumor lesion and no sign of progression). Five of 10 patients treated within 8 weeks of the detection of advanced cancer and 2 of 23 patients treated more than 8 weeks after the detection of cancer had complete or partial recovery. Toxicity was moderate (nausea, vomiting, diarrhea, stomatitis, and severe alopecia), although it necessitated a change to another regimen for one patient. One patient refused further chemotherapy, and one patient died due to severe bone marrow toxicity. The results suggest that the highest response rate to chemotherapy in advanced colorectal cancer is found in patients with recently detected lesions.

6575 FATAL OUTCOME IN A CHILD WITH PSEUDOMEMBRANOUS COLITIS.

(Eng.) Fee, H. J.; Kearney, J. P.; Ament, M. E.; Fonkalsrud, E. W. (UCLA Sch. Medicine, Los Angeles, CA 90024). *J. Pediatr. Surg.* 19(6):959-963; 1975.

The case of a 26-month-old boy in whom fatal pseudomembranous colitis developed after the administration of several antibiotics is presented. The patient was hospitalized for fever, nonbloody diarrhea, and leukocytosis. During the preceding 3 days of illness, he had been treated with an i.m. dose of streptomycin. On admission, erythromycin treatment was initiated, but the therapy was changed to i.v. ampicillin and i.m. kanamycin. The next day, the treatment was changed to i.v. chloromycetin because of worsening diarrhea and increasing fever. After the onset of abdominal distension and vomiting, the therapy was again changed to ampicillin and gentamicin. The diagnosis of antibiotic-induced pseudomembranous colitis was made on the basis of several factors: worsening diarrhea and appearance of fever acutely after antibiotics were started, stool cultures free of pathogens, and proctosigmoidoscopy revealing the classic morphologic changes of pseudomembranous colitis (mucosal edema and friability with the presence of multiple plaques). Despite the absence of free intraabdominal air on repeated radiograms, the patient's progressively deteriorating course, with clear evidence of peritonitis, made the diagnosis of perforated colon likely. Laparotomy revealed that the colon was necrotic, with denuded epithelium; the submucosa was hemorrhagic, and there were several perforations. A proctocolectomy and ileostomy were performed, and the patient was started on i.v. gentamicin and cleocin. The patient's condition improved until the eighth postoperative day, when his symptoms returned. Despite intraabdominal catheterization, irrigation of the peritoneal cavity with a cephalothin solution, and treatment with methyl prednisolone acetate (2 mg/kg, i.v.), sepsis recurred. Multiple dilated venous collaterals developed over the entire abdominal and anterior chest wall, suggesting venous obstruction with portal hypertension. Liver function deteriorated, and the patient died in cardiorespiratory arrest. Postmortem examination revealed abscesses involving 80% of the liver. Neither vena caval nor portal vein obstruction was found. Proctosigmoidoscopic examination should be used routinely to detect pseudomembranous colitis in the evaluation of both adults and children with refractory diarrhea following antibiotic therapy.

6576 FATAL PSEUDOMEMBRANOUS ENTEROCOLITIS FOLLOWING CLINDAMYCIN THERAPY.

(Eng.) Dane, T. E. B.; King, E. G. (Craigavon Area Hosp., Craigavon, Co. Armagh, N. Ireland). *Br. J. Surg.* 63(4): 305-308; 1976.

A fatal case of pseudomembranous enterocolitis occurring after p.o. and i.v. clindamycin therapy is reported in a 55-yr-old man who had undergone resection of the sigmoid colon for diverticular disease. Ten centimeters of diseased bowel at the junction of the descending and sigmoid colon were resected with a two-layer end-to-end anastomosis. A small abscess cavity was opened during mobilization of the diseased colon. Because of this, the patient was given 300 mg clindamycin i.v., and the anastomosis was protected by dividing the transverse colon and establishing the proximal end as an end colostomy. The initial postoperative progress was satisfactory, and clindamycin therapy was continued for 6 days (150 mg, i.v., 4-hourly for 4 days and 300 mg, p.o., 6-hourly for 2 days). On the 11th postoperative day, the patient developed abdominal pain, vomiting, and subsequent watery colostomy drainage and vascular collapse. The course of the disease process was complicated by delayed recognition of the pseudomembranous enterocolitis, further therapy with clindamycin (450 mg, i.v., 4-hourly), sepsis, and renal failure. At laparotomy, the cecum and terminal 180 cm of ileum were grossly edematous and discolored, but the jejunum and the colon distal to the colostomy were normal. Gram-negative septicemia was discovered, and therapy with penicillin, chloramphenicol, and methylprednisolone was begun. Clindamycin was discontinued. Although the patient's condition improved, massive hematemesis caused his death. At autopsy, the unusual sparing of the upper small bowel and the large bowel distal to the colostomy was confirmed histologically. The stomach contained fresh blood, and its mucosa had many superficial erosions; the gastric hemorrhage from these erosions was probably related to stress and corticosteroid therapy. The most interesting features of this case are the extensive small bowel involvement by the disease and the sharp demarcation of the process by the transverse colostomy, with complete sparing of the distal bowel. The latter finding suggests that local factors in the bowel are at least contributory in the pathophysiology of clindamycin-associated pseudomembranous enterocolitis.

6577 BRAN TABLETS AND DIVERTICULAR DISEASE.

(Eng.) Taylor, I.; Duthie, H. L. (Royal Infirmary, Sheffield, England). *Br. Med. J.* 1(6016): 988-990; 1976.

High-roughage diet (HRD), Normacol plus antispasmodic, and bran tablets (18 g/day) were compared in a crossover trial in 20 patients with symptomatic diverticular disease. Half of the patients received either HRD for 1 month or Normacol plus antispasmodic for 1 month, and half received bran tablets for 1 month. Treatments were then crossed over. All patients experienced some improvement in symptoms (degree of pain, bowel habit, and amount of distension) with each treatment; 20% were entirely asymptomatic after treatment with HRD, 40% after Normacol, and 60% after bran tablets. The mean stool weight before treatment was 79 g. On both Normacol and bran tablets, the stool weight increased significantly, to 105 g and 121 g, resp., after 1 month. The mean transit time before treatment was 96.6 hr, which was significantly decreased by all three treatments (76.4 hr with HRD, 71.7 hr with Normacol, and 56.1 hr with bran tablets). Bran tablets were significantly more effective than either Normacol ($p<0.05$) or HRD ($p<0.001$). The mean percentage of motility before treatment (14.2%) was reduced to within normal limits (6.5%) by bran tablets, but not by HRD or Normacol. Rapid electrical activity of colonic smooth muscle was present in 80% of the subjects before treatment; 50%, 60%, and 40% of patients had rapid activity after treatment with HRD, Normacol, and bran, resp. These results suggest that in diverticular disease, all indices of colonic pathophysiology can be restored to normal. The theory that diverticular disease results from a normal colon being subjected to abnormal dietary stress rather than from a primary or constitutional colonic abnormality is supported. The bran tablets were both convenient and acceptable.

6578 THE NATURAL HISTORY OF DIVERTICULAR DISEASE OF THE COLON. A REVIEW OF 238 CASES.

(Eng.) Podesta, M. T.; Pace, J. L. (Dept. Anatomy, Royal Univ. Malta, Malta). *Chir. Gastroenterol.* 9(3):371-374; 1975.

A review of 238 patients with the radiological diagnosis of diverticular disease is presented, with regard to the age and sex distribution, the mode of presentation, and the course and management of the disease. The male:female ratio was 128:110. In both sexes, more cases presented in the seventh decade than in any other. The average age among 25 patients who had extensive colonic involvement (i.e., beyond the left colon) was 63.4 yr, while patients with less extensive disease had an average age of 62.4 yr. The sigmoid colon alone was involved in 49% of the cases, while involvement of the descending colon and/or the sigmoid colon occurred in another 34.8% of the cases. Thirty-six percent of the patients with extensive colonic involvement had symptoms for less than 1 month, while 25% of patients with sigmoid disease and 41% of patients with involvement of the sigmoid plus descending colon had less than 1-month histories. Fifty-nine percent of the patients required hospitalization. The correct diagnosis was made in only 26 of 216 hospitalized patients. Only 42 patients were treated surgically. The usual operative procedure in the acute stage was appendectomy and cecostomy, or colostomy. One stage resection was the most common elective procedure. In 40% of cases, elective surgery was undertaken primarily for concomitant malignant disease. Of the 42 surgically treated patients, 21.4% died, 7.1% have severe symptoms, 35.7% have mild symptoms, and 19.0% are asymptomatic. Of the 196 patients who did not undergo surgery, 17.9% are dead, 6.1% have severe symptoms, 24.0% have mild symptoms, and 21.4% are asymptomatic. Associated pathological conditions included cholecystitis and/or cholelithiasis (22 patients), gastric and/or duodenal ulcer (14), appendicitis (17), hiatus hernia (15), other hernias (54), colonic malignancy (15), and malignancy elsewhere (15).

6579 CHRONIC ADYNAMIC BOWEL SIMULATING HIRSCHSPRUNG'S DISEASE.

(Eng.) Kapila, L.; Haberkorn, S.; Nixon, H. H. (Children's Hosp., Chestnut Grove, Nottingham, England). *J. Pediatr. Surg.* 10(6):885-892; 1975.

A case of chronic adynamic bowel simulating Hirschsprung's disease is reported in a female infant, and three previous cases are reviewed. Functional intestinal obstruction could be excluded in all cases. All had similar presenting features, including a head circumference below normal. In spite of the presence of many features of Hirschsprung's disease, such as vomiting, abdominal distension, and constipation, normal ganglia were present. There was also an absense of bowel sounds. In all cases, conservative treatment failed, and decompression by colostomy or ileostomy failed, until assisted by irrigations or drugs. In all cases, the bowel was thin, dilated, and adynamic. In the present case, the only clue to etiology was a raised immunoglobulin M level and culture of cytomegalovirus from urine specimens. The other patients were not studied for virus. The bowel histology was normal in all cases. Therapy with cholinergic drugs or alpha or beta blockers was ineffective. In the present case, cerulein produced intestinal activity, and its use was continued for 6 months with no side effects. The patient died of complications of a closed loop obstruction resulting from adhesions. Of the three previous cases, two died; the third recovered after treatment with i.v. fluids, hydrocortisone, and methicillin. It is suggested that cerulein be investigated as a treatment for this condition.

6580 CALCIFIED INTRALUMINAL MECONIUM IN NEWBORN MALES WITH IMPERFORATE ANUS: ENTEROLITHIASIS IN THE NEWBORN.

(Eng.) Berdon, W. E.; Baker, D. H.; Wigger, H. J.; Mitsudo, S. M.; Williams, H.; Kaufmann, H. J.; Shapiro, L. (Babies Hosp., Columbia-Presbyterian Medical Center, New York, NY 10032). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 125(2):449-455; 1975.

Five cases in which multiple foci of calcified meconium were noted on preoperative abdominal roentgenograms of newborn males with imperforate anus are reported, and three previous cases are reviewed. In the five cases studied, all had supralevator rectal atresia. In four, fistula was demonstrated between the distal colon and either the bladder or urethra; in the fifth, autopsy was incomplete. None had meconium peritonitis. Rectourinary fistula was also present in one of the three reviewed cases. In a second, a fistula may have been present, but was missed. In all cases, the calcifications were entirely intraluminal. The findings suggest that the calcifications may represent an interaction between urine and meconium, and demonstrate that in male infants with imperforate anus, intraluminal meconium enterolithiasis is strongly suggestive of a rectourinary fistula.

6581 ACUTE PERFORATION OF THE COLON ASSOCIATED WITH CHRONIC CORTICOSTEROID THERAPY.

(Eng.) Warshaw, A. L.; Welch, J. P.; Ottinger, L. W. (Massachusetts General Hosp., Boston, MA 02114). *Am. J. Surg.* 131(4):442-446; 1976.

The clinical findings in 13 patients treated with steroids who developed acute perforation of the colon are presented. Steroid administration averaged 3.4 yr (11 days to 10 yr), and only three patients received steroids for less than 2 months. The steroids included prednisone (5-100 mg/day) and dexamethasone (4-32 mg/day). The most common presenting complaint was abdominal pain (92%); abdominal tenderness occurred in all patients, and fever occurred in 92%. The clinical and laboratory findings were considered conclusive enough to warrant urgent surgical intervention in 10 patients, although the diagnosis of colonic perforation was correctly made prior to operation only three times Failure to recognize that a perforation had occurred delayed or deterred surgical exploration in three cases. In 9 of 11 patients for whom there was surgical or autopsy information, there was no walling off of the perforation site or adherence of adjacent viscera. The perforation was most often found in the sigmoid colon (8 patients), but also occurred in the cecum (3), at the hepatic flexure (1), and at multiple points along the transverse and descending colon (1). In five patients, the perforation was located close to diverticula and could not be distinguished pathologically from perforated diverticulitis occurring in the absence of steroid therapy. In the other eight patients, the perforations were distinctly unusual. In five patients, single punched-out transmural ulcers were found. Three of the five patients who underwent resection of the perforated segment survived. Four patients treated by colostomy and drainage survived, but one whose perforated hepatic flexure was exteriorized did not. The evidence suggests that corticosteroids can be responsible for ulceration and perforation of the colon, either by direct injury or by interference with normal mechanisms of bowel repair.

6582 Polyposis coli ASSOCIATED WITH FIBROSIS OF MESENTERY, MESOCOLON AND RETROPERITONEAL TISSUES: A RARE VARIANT OF GARDNER'S SYNDROME. (Eng.) Carneiro Chaves, F. J. Z.; Cruz, I.; Lopes, C.; De Morais, M. (Hosp. Santa Maria, Lisbon 4, Portugal). *Am. J. Gastroenterol.* 65(2):163-167; 1976.

The rare case of a 48-yr-old black man with multiple colonic polyposis, cutaneous and soft tissue tumors, and multiple osteomatosis (Gardner's syndrome) is presented. The patient had a 1-yr history of abdominal pain and rectal bleeding. A tender mass was palpable on the right flank. Sigmoidoscopy and barium enema examination revealed multiple polyps. A radiographic bone survey demonstrated diffuse areas of sclerosis in the cancellous bone of the maxilla and mandible. The right frontal sinus was opacified. There were supernumerary and unerupted teeth, and all long bones had an irregular, thickened cortex. At laparotomy, the small bowel was found to be suspended from a very hard and retracted mesentery. Fibrosis had progressed to the cecum and ascending colon. There was also fibrosis of the mesocolon extending to the posterior peritoneum. Colectomy was not possible. Histologic examination of biopsy specimens of the mesentery and retroperitoneal tissues revealed a noninflammatory fibrous tissue hyalinized in some areas. Despite continuing abdominal pain and rectal bleeding over a 2-yr follow-up period, the patient did not lose weight, and there was no evidence of colonic malignancy. This is the first reported case of Gardner's syndrome occurring in an African black patient.

LARGE INTESTINE

Ulcerative Colitis

6633 TISSUE DEMONSTRATION OF CARCINOEMBRYONIC ANTIGEN (CEA) IN ULCERATIVE COLITIS. (Eng.) Isaacson, P. (Southampton Univ. Hosp., Southampton, England). *Gut* 17(7):561-567; 1976.

To determine whether premalignant foci can be identified by an increased carcinoembryonic antigen (CEA) content, protocolectomy specimens from nine patients with ulcerative colitis were examined by an immunoperoxidase technique. Goat antiCEA and horse antigoat immunoglobulin were used. Only carcinoma specimens and mucosa specimens showing premalignant change stained positively for CEA. Areas of active or chronic inactive disease were negative, even when inflammatory dysplasia was present. Metaplastic Paneth cells stained positively, as did Paneth cells from the ileum of one patient with ileorectal anastomosis. The results show that detection of CEA by this method is a reliable indicator of premalignant change or carcinoma-*in-situ* in ulcerative colitis.

PANCREAS

Pancreatitis

6645 HEMATEMESIS AND MELENA AS THE FIRST SYMPTOMS OF PANCREATIC DISEASE. (Ita.) Porta, G. C.; Scotti, F.; Rossi, G. M.; Gramazio, G. F.; Taglibue, M. (Ospedale S. Gerardo Tintori, Circolo di Monza, Italy). *Arch. Ital. Chir.* 98(4):491-499; 1974.

Four cases (4 men, aged 40-48 yr) of pancreatic disease are reported. The first symptoms were intestinal hemorrhages caused by the rupture of the gastroesophageal varices which in turn was caused by segmentary portal hypertension. Splenoportography was crucial for the diagnosis and choice of surgery. In the first case (diffuse pancreatitis), splenoportography revealed complete obstruction of the splenic vein; this was indicative of severe retropancreatic inflammation, a pancreatectomy was impossible, and a splenectomy was performed because of the irreversability of the stenosis. In the second case (a pseudocyst), splenoportography revealed a stenosed splenoportal vein; portal hypertension disappeared following a simple by-pass. In the third case, (pseudocyst), examination revealed an enlarged spleen, an obstructive vascular lesion, and a normal splenic vein beyond the hilus of the spleen; a splenectomy was performed. In the fourth case (an adenocarcinoma), the splenic vein was completely obstructed; surgery removed a neoplasia of the tail and body of the pancreas infiltrating the hilus of the spleen. A gastroenteroanastomosis was performed because of stenosis. Thus, a digestive hemorrhage can be of pancreatic origin. Angiography, and especially splenoportography, are essential for the diagnosis and choice of treatment.

6646 "SENILE" CHRONIC PANCREATITIS—A NEW NOSOLOGICAL ENTITY? OBSERVATION OF 38 CASES. INDICATIONS OF VASCULAR ETIOLOGY AND RELATIONSHIPS WITH PRIMARY PAINLESS CHRONIC PANCREATITIS. (Ger.) Ammann, R.; Sulser, H. (Departement fur Innere Medizin, Kantonsspital, Ramistrasse 100, CH-8091 Zurich, Switzerland). *Schweiz. Med. Wochenschr.* 106(3):429-437; 1976.

The clinical picture, differential diagnosis, complications, histology, and prognosis of idiopathic senile chronic pancreatitis is analyzed. Of 170 patients with confirmed chronic pancreatitis (CP), the pathogenesis of 47, including 38 "senile" cases (31 men), remained unclear. Nine patients averaged 28.7 yr of age, and 38 averaged 61.7 yr. The clinical course was painless in 28 of the 38 in the senile group, with weight loss and diarrhea being the typical symptoms; alcohol consumption was reported in 17. Pelvic or lower limb vascular disturbances occurred in 12, and coronary stigmata in 9. Frank exocrine or endocrine pancreatic deficit was present in the majority. Local complications (pseudocysts or obstructive icterus) were rare, and in no case were they or the parent pancreatitis responsible for the mortality of 17 at the average age of 68 yr. Idiopathic senile CP histology was uniform: focal acini atrophy, extensive intra- and perilobular sclerosis, minimal inflammatory infiltration, and no fresh necroses or calcification. A majority of idiopathic senile CP patients presented with one or more atherosclerotic risk factors, suggesting a vascular factor in its pathogenesis. In contrast to painless chronic pancreatitis, which is a syndrome, idiopathic senile CP is thought to represent an etiologically uniform disease state.

6647 FUNCTIONAL RESPIRATORY DISTURBANCES IN PATIENTS WITH CHRONIC PANCREATITIS. (Fre.) Paris, J.; Guerrin, F.; Gerard, A.; Weber, J. C. (Hopital Regional de Lille, 1, place de Verdun, 59000 Lille, France). *Bull. Acad. Natl. Med. (Paris)* 159(5):410-416; 1975.

Pulmonary function studies were undertaken in 57 men (19 to 65 yr old; average age, 41 yr) hospitalized for chronic pancreatitis. Symptoms of disease had been present for several months to 10 yr (average, 2 yr and 4 months). Diabetes was present clinically in 4, and latent diabetes was present in 15. A careful study revealed 22 patients with a history of pneumopathology (chronic respiratory insufficiency, x-ray evidence of tuberculosis or other abnormalities, or respiratory infection); these patients were considered as a separate group. Blood gas studies, spirometry, carbon monoxide transfer, and alveolar exchange revealed four categories of malfunction: (1) ventilation deficit in 9, (2) total carbon monoxide transfer reduced by more than 15% in 21, (3) light or moderate hypocapnia with normocapnia in 22, and (4) decreased alveolar exchange and pulmonary passage of oxygen in 8/12 cases tested for changes in ventilation efficacy. Respiratory disorders were often associated in the same patient and 32/35 patients in the group with no history of pneumopathology had evidence of malfunction. The other group of 22 patients had a higher percentage of respiratory disorders. The absence of a relation between the severity or duration of the pancreatitis and the respiratory malfunction appears to rule out their interdependence.

6658 USE OF KINESIMETRY FOR THE EXPLORATION OF THE BILE DUCTS.

(Fre.) Larrieu, H. (Hopital Antoine-Beclere, F 92140 Clamart, France). *J. Radiol. Electrol. Med. Nucl.* 56(8/9):633-634; 1975.

The value of kinesimetry, as compared to cholangiography, radiomanometry, and other techniques for studying bile duct pathology was evaluated. Kinesimetry provided more data and the method can be utilized peroperatively at the start of operative procedures; however, morphine and atropine must be excluded from anesthesia. Kinesimetry can measure bile duct pressure postoperatively by the use of a Kehr drain in the unanesthetized patient. Pressure in bile duct in response to perfusion of 2-10 ml/min of opaque medium is measured by a photoelectric cell system. The examination usually lasts about 30 min and is followed radiographically. Kinesimetry is the only method of diagnosis for an enlarged, unobstructed common bile duct with low pressure, a low pressure Wirsungian reflux, and duodeno-oddian synergy (effect of disturbed duodenal peristalsis on biliary pressure). More important, the method diagnoses the presence of a functioning sphincter of Oddi and prevents unnecessary sphincterotomies.

6659 BILE ACIDS IN CLINICAL MEDICINE. DISTURBANCES IN THE ENTEROHEPATIC CIRCULATION.

(Eng.) Manier, J. W. (Marshfield Clinic, 1000 North Oak Ave., Marshfield, WS 54449). *Wis. Med. J.* 75(5):S40-42; 1976.

Three syndromes that result in interruption of the enterohepatic circulation of bile acids and their detection and treatment are described. The first syndrome is deconjugation of bile acids in the small intestine due to bacterial overgrowth. This results from any situation that interferes with peristalsis (surgically constructed blind loops, enterocolonic fistuli, strictures, diverticuli, and diseases such as scleroderma, amyloidosis, and pseudo-obstruction). The two other syndromes result from the bypass or resection of varying amounts of ileum. If the loss is small (30-100 cm), the liver can synthesize sufficient bile acids to compensate for the fecal loss. There will, however, be an increase in bile acids presented to the colon, which can produce excessive colonic water and electrolyte secretion with resultant watery diarrhea. In patients with a greater than 100-cm ileal loss, the loss of bile acid absorptive sites is so great that the liver can no longer synthesize sufficient replacements. Insufficient bile acids are present for micelle formation, and steatorrhea results. The administration of a bile acid sequestering resin, cholestyramine, has resulted in a correction of diarrhea resulting from the loss of less than 100 cm of ileum. In patients with a loss of greater 100 cm, limitation of long chain triglycerides and their replacement with medium and short chain triglycerides results in improvement, since the medium and short chain triglycerides can be absorbed without micelles. By having subjects who had previously ingested ^{14}C-labeled choleglycine breathe into a basic solution (hyamine) to which a color indicator (phenothalein) has been added, a direct quantitation of the degree of bacterial deconjugation can be obtained by measuring the amount of trapped ^{14}C by liquid scintillation. By measuring fecal radioactivity, the syndromes can be further differentiated.

6660 THE BSP TEST WITH CONTINUOUS PERFUSION IN THE DIAGNOSIS AND MONITORING OF THERAPY FOR HEPATOBILIARY DISEASE.

(Fre.) Borg, R. (Universite Bordeaux II, France). *Rev. Fr. Gastroenterol.* (106):47, 49, 51-52; 1975.

A method for evaluating liver function experimentally by the continuous perfusion of BSP is described. After i.v. perfusion of BSP at a rate of 3.82 mg/min, femoral artery and hepatic vein concentrations increased linearly; the concentrations always differed by 3.2 mg. If BSP is injected in high concentrations over a prolonged period of time, the quantity excreted in the bile reaches a maximum (T_m). T_m also theoretically represents maximum hepatic fixation. A formula was derived for evaluating liver function based on the BSP level in the plasma compared to the maximum BSP level excreted by bile and the variation of plasma levels as a function of time. This method permits the study of the influence of treatment on the outcome of hepatobiliary disease such as hepatic cholestasis.

6661 DIAGNOSTIC VALUE OF γ-GLUTAMYL TRANSPEPTIDASE IN LIVER DISEASES.

(Ger.) Thefeld, W. (Institut fur Sozialmedizin und Epidemiologie des Bundesgesundheitsamtes, 1 Berlin 33, Thielallee 88/92, W. Germany). *Med. Welt* 26(47):2139-2141; 1975.

A review of the literature on the diagnostic potential of gamma-glutamyl transpeptidase (GGT) in liver pathology is presented. The percentage of patients with elevated GGT levels shows a wide variation between liver diseases: 82-100% for acute virus hepatitis, 0-94% for chronic persisting hepatitis, 44-100% for acute chronic hepatitis, 74-100% for posthepatitic cirrhosis, 68-100% for fatty liver, 93-100% for cholestasis, 98-100% for cholecystitis, 87-100% for liver metastases, and 92-96% for hepatosteatosis. There is a consensus that the normal GGT range is 23-38 U/l for men and 14-35 U/l for women, and that the GGT level bears no correlation with levels of alkaline phosphatase, leucine aminopeptidase, or transaminases (TR). GGT data contribute no more information than TR in acute viral hepatitis. Increases in the relatively low GGT elevation in chronic persisting hepatitis can be prognostic of the onset of the active form. GGT has a supplementary role in differentiating ethanol hepatitis, fatty liver, and posthepatitic cirrhosis. GGT sensitivity to short-term effects of alcohol could not be confirmed. In obstructive jaundice, the high elevations have diagnostic value in conjunction with transaminase depression. High increases can suggest cholangitis, but the picture with biliary cirrhosis is equivocal. GGT is diagnostically crucial in cirrhotogenic primary liver carcinoma and in metastatic disease where histology is impossible. Its behavior in xenogeneic hepatotoxicity is paradoxical.

6662 IMMUNOPATHOLOGICAL PHENOMENA IN LIVER DISEASES. (Ger.) Lehmann, H.-U.; Renger, F.; Dokert, B.; Morenz, J.; Zugehor, M. (Med. Klinik der Med. Akademie, 8019 Dresden, Fetscherstrasse 74, E. Germany). *Z. Gesamte Inn. Med.* 30(23):258-261; 1975.

The prognostic, differential diagnostic, and therapeutic indicator roles of autoantibodies in liver pathology were explored in 400 patients. The highest antibody titer against mitochondria occurred in all eight patients with primary biliary cirrhosis; positive responses were achieved in 35 of 53 patients with liver cirrhosis, 32 of 63 with infectious hepatitis, 11 of 23 with chronic persisting hepatitis, and 28 of 38 with chronic active hepatitis. Against smooth muscle, there were positive responses in 16 patients with chronic active hepatitis, 6 with chronic persisting hepatitis, 9 with cirrhosis, 4 with infectious hepatitis, and 4 with biliary cirrhosis. Against cell nuclei, chronic active hepatitis showed the highest titer, with responses in eight patients; responses were obtained from none of the patients with chronic persisting hepatitis, from one with infectious hepatitis, one with cirrhosis, and one with biliary cirrhosis. The acute viral phase of hepatitis was weakly positive, and ethanol cirrhosis, completely negative. Very weak responses were elicited to hepatitis B antigen in all hepatitis groups. All strongly positive chronic active hepatitis patients were hepatitis B-negative. Based on antibody response, two patients with biliary cirrhosis and one with chronic active hepatitis were successfully treated with prednisone or a prednisone-azathioprine combination. If 1:160 is established as the limiting titer, the antibody spectrum appears to be valuable in differential diagnosis.

6663 LIPOPROTEINS IN LIVER DISEASES. (Ger.) Seidel, D. (Med. Univ.-Klinik [Ludolf-Krehl-Klinik], 69 Heidelberg, Bergheimer Strasse 58, W. Germany). *Med. Welt* 26(47):2131-2133; 1975.

The current status of elevated plasma lipoproteins (LP) in the differential diagnosis of liver dysfunction is reviewed. The abnormal LP-X is the most sensitive test for intra- or extrahepatic cholestasis. The presence of hypertriglyceridemia, with the accumulation of triglyceride-rich serum LP due to a lipase deficiency, can also be pathognomic of cholestasis-conditioned liver disease. The disappearance of pre-beta- and alpha-LP bands in agarose electrophoresis, a frequent sign of liver obstruction independent of pathogenesis, is caused by a defect in apo-LPA, whose binding potential for certain lipid fractions is diminished or abolished. The character of lecithin, cholesterol acyltransferase activity in liver disease, is paradigmatic.

6664 CURRENT CONCEPTS OF POSTOPERATIVE HEPATIC DYSFUNCTION. (Eng.) LaMont, J. T.; Isselbacher, K. J. (Peter Bent Brigham Hosp., Boston, MA). *Conn. Med.* 39(8):461-464; 1975.

The pathophysiologic consequences of surgery and anesthesia on hepatic function are reviewed, and the various clinical presentations of postoperative jaundice are described. Approximately one-third to one-half of surgical patients develop minor postoperative abnormalities of liver function, while significant jaundice (bilirubin, 2.5 mg%) occurs in 1% or less of patients. Although the exact pathophysiology of postoperative jaundice is unknown, a number of factors have been implicated, including hypotension, hypoxemia, sepsis, blood transfusion, and allergic or toxic reactions to drugs and anesthetic agents. Since most cases of postoperative jaundice are due to damage to the hepatocyte rather than extrahepatic biliary obstruction, surgery is rarely necessary.

6665 MAJOR HEPATIC VEIN LIGATION NECESSITATED BY BLUNT ABDOMINAL TRAUMA. (Eng.) DePinto, D. J.; Mucha, S. J.; Powers, P. C. (Naval Regional Medical Center, 17th and Pattison Ave., Philadelphia, PA 19145). *Ann. Surg.* 183(3):243-246; 1976.

An unusual case involving avulsion of the middle and left hepatic veins secondary to blunt trauma is presented. The patient, a 19-yr-old man, underwent exploratory laparotomy 4 hr after an automobile accident. An actively bleeding 6-cm laceration on the anterosuperior surface of the liver was found. Although several bleeding arterial branches were ligated, blood continued to accumulate. Massive hemorrhage, resulting from attempts to visualize the bleeding source, suggested retrohepatic vena cava and/or hepatic vein disruption. The porta hepatis was occluded and the bleeding was tamponaded. Median sternotomy was performed, and rapid transfusions into the retrohepatic vena cava via a chest catheter were performed. The diaphragm was split to the vena cava, and the tamponade was slowly removed. Blood loss was reduced, and completion of the traumatic hepatic fracture allowed exposure of the anterior surface of the retrohepatic vena cava. Avulsion of the middle and left hepatic veins necessitated their ligation. The defect in the vena cava was closed with a continuous suture. The intraluminal shunt was removed, and 90 min of intermittent porta hepatis occlusion was terminated. Immediately after the ligation of the middle and left hepatic veins, the left lobe became canotic; however, 15-30 min after restoration of the flow within the porta hepatis, the appearance of the parenchyma had improved, and left hepatectomy was unnecessary. The postoperative course was relatively uncomplicated, and the patient is asymptomatic 10 months after the injury. Although serial hepatic scans 10 days after surgery showed nonvisualization of the left lobe and poor uptake within the right lobe, scans done 24 and 50 days post injury demonstrated near normal perfusion of the right lobe and delayed and slightly decreased perfusion of the left lobe. Ten months after operation, the scan was normal except for a small wedge-shaped defect. This case demonstrates that if after ligating major hepatic veins, the condition of the obstructed parenchyma stabilizes or improves under direct observation and if the condition of the patient does not deteriorate, resection may not be required.

6666 GASTROJEJUNOSTOMY INHIBITS POSTSHUNT SIDEROSIS.

(Eng.) Doberneck, R. C.; Fischer, R.; Smith, D. (Sch. Medicine, Univ. New Mexico, 2211 Lomas Blvd., NE, Albuquerque, NM 87131). *Surgery* 78(3):334-338; 1975.

The mechanism for the development of hemosiderosis following portacaval shunt was investigated in 26 dogs. Thirteen of 14 dogs developed marked increases in hepatic hemosiderin after the construction of a portacaval shunt, whereas only 3/12 dogs developed such siderosis after the duodenum was excluded by the construction of a portacaval shunt and end-to-side gastrojejunostomy. The mean level of splenic hemosiderin (2.2 on a graded scale of 0-4, in which 4 represents the highest amount of hemosiderin) was increased markedly in dogs with portacaval shunt, but increased minimally in dogs with portacaval shunt and gastrojejunostomy (0.91; control level, 0.8). Rib marrow fat increased slightly in dogs with portacaval shunt (0.45; control, 0.38) and decreased slightly in dogs with portacaval shunt and gastrojejunostomy (0.32). Continued iron absorption appears to account for the development of postshunt siderosis, and the addition of gastrojejunostomy ameliorates postshunt siderosis by diminishing iron absorption.

6667 LIVER INJURY.

(Eng.) Anonymous. (No affiliation given). *Br. Med. J.* 3(5983): 558; 1975.

A brief review of the mortality rate, treatment, and diagnosis of liver injury is presented. Since the 1960's, there has been a considerable improvement in survival after liver injury. Among 270 patients in one series, only 5 with stab wounds died, largely the result of wound infection and pulmonary atelectasis. The mortality from blunt liver injury has shown the most dramatic decrease—from 60% to 30% or less. Among the reasons for this improvement were the change from the packing of liver wounds to suture ligation of bleeding points, the employment of antibiotics, and appropriate drainage. These methods, together with debridement of devitalized liver tissue and occasional hepatic lobectomy for extensive shattering wounds, have been effective in the treatment of some injuries. Some authors have recently shown that hepatic arterial ligation, combined with debridement, is valuable in the treatment of some cases of major liver damage. Up to 30% of patients, especially those with blunt injury, may present without gross signs of intra-abdominal damage. Mortality and morbidity are related to delay in treatment, and laparotomy on suspicion of liver injury is justifiable. Special investigations (liver scan, selective celiac axis angiography, abdominal paracentesis, and peritoneal lavage) are not generally available and may give false-negative results. They may, however, be valuable in detecting the late-presenting intrahepatic hematoma, and they may detect damage before the need for laparotomy becomes evident on physical examination.

6668 ANTIBIOTIC CONCENTRATIONS IN HEPATIC INTERSTITIAL AND WOUND FLUID.

(Eng.) Waterman, N. G.; Raff, M. J.; Scharfenberger, L.; Barnwell, P. A. (Dept. Surgery, Price Inst., Louisville, KY). *Surg. Gynecol. Obstet.* 142(2):235-238; 1976.

Antibiotic concentrations in serum, bile, hepatic interstitial fluid, and interstitial fluid of the soft tissues of the abdominal wall were measured after the i.v. administration of cephalothin, cefazolin, ampicillin, tetracycline (all at 20 mg/kg), and gentamicin (1.1 mg/kg) to dogs. Cephalothin, cefazolin, ampicillin, and tetracycline appeared in the bile at concentrations greater than the simultaneous serum levels. Biliary cephalothin decreased from 75 mg/ml at 1 hr to 50 mg/ml at 4 hr. The 1- and 4-hr biliary levels of cefazolin were 400 mg/ml and 350 mg/ml, resp.; of ampicillin, 125 mg/ml and 75 mg/ml, resp.; and of tetracycline, 100 mg/ml and 150 mg/ml, resp. During the period from 1 to 4 hr after the administration of ampicillin or cefazolin, concentrations of these antibiotics in the serum and interstitial fluids of the soft tissue and liver were similar. The levels of tetracycline in the serum remained approximately twice those of the soft tissue and hepatic interstitial fluid over the same period. Tetracycline levels in these two interstitial fluids were not significantly different from each other at any time. Serum cephalothin levels decreased rapidly after 1 hr, becoming equivalent to the low hepatic interstitial fluid levels by 3 hr. Cefazolin concentrations in serum and both interstitial fluids were similar throughout the entire period of measurement, and the disappearance of cefazolin from these compartments occurred at a slower rate than with cephalothin. Serum gentamicin concentrations exceeded biliary levels only during the first 2 hr. There were no significant differences in the gentamicin levels between the two interstitial fluids at any time. The results suggest that the tendency of an antibiotic to concentrate in bile does not correlate with levels achieved in hepatic interstitial fluid or in wound exudates; the latter are closely similar to soft tissue fluids with respect to penetration by antimicrobial agents. The selection of an antimicrobial agent for the therapy of hepatic parenchymal infection or obstructive cholecystitis should, therefore, be based on susceptibilities of the suspected organism rather than on the relative tendencies of various agents to be concentrated in bile.

6669 DIFFUSE LIVER INJURY IN AMEBIC ABSCESS OF THE LIVER: AN ELECTRON MICROSCOPIC STUDY.

(Eng.) Tandon, B. N.; Tandon, H. D.; Ravi, V. V.; Gandhi, P. C. (All-India Inst. Medical Sci., New Delhi 110016, India). *Exp. Mol. Pathol.* 23(2): 155-163; 1975.

Liver biopsies of eight patients with amebic liver abscesses were studied by light and electron microscopy, to obtain evidence of diffuse parenchymal injury. In four patients, the studies were repeated on complete clinical recovery, after specific antiamebic treatment. Light microscopic changes were nonspecific and suggested diffuse parenchymal injury in some biopsy specimens. The ultrastructural changes in the hepatocytes were consistent in all patients; these included dilatation of endoplasmic reticulum, vesicle formation and fragmentation, reduction in microsomes, and mitochondrial abnormalities. Many cells showed features of regenerative activity. These changes are similar to those reported in patients with the nonsuppurative form of the disease, where the changes were less severe and suggestive of more active regeneration. The changes were reversed on treatment. These observations suggest that nonsuppurative hepatic amebiasis is a distinct pathologic entity, even though the light microscopic changes by themselves are not specific.

6670 SIGNIFICANCE OF SERUM LACTIC DEHYDROGENASE ENZYME IN HEPATIC AMOEBIASIS.

(Eng.) Mahajan, R. C.; Singh, K.; Ganguly, N. K.; Chitkara, N. L. (Postgraduate Inst. Medical Education Res., Chandigarh-160011, India). *Indian J. Med. Res.* 63 (7):1006-1009; 1975.

Because elevated levels of serum lactic dehydrogenase (LDH) have been observed in various diseases, the level of this enzyme was determined in the sera of 25 patients with proven amebic liver abscess, 50 healthy controls, 10 control patients with infectious hepatitis, 10 with noncirrhotic portal fibrosis, 5 with hepatoma, and 5 with myocardial infarction. In the sera from normal controls, the LDH level ranged between 40 and 230 mIU; levels of 240 mIU or more were considered elevated. Raised serum LDH, ranging from 266 to 948 mIU, occurred in 23 of the 25 patients with amebic liver abscess in the acute phase. The LDH level returned to normal in all but two patients at 1 month after the complete cure of the disease. Elevated LDH occurred in eight cases of infectious hepatitis in the control patients, three cases of noncirrhotic portal fibrosis, all cases of hepatoma, and in four cases of myocardial infarction. The results suggest that LDH determination may be a useful index for the cure of invasive hepatic amebiasis.

6671 AMOEBIC LIVER ABSCESS PRESENTING THIRTY-TWO YEARS AFTER ACUTE AMOEBIC DYSENTERY.

(Eng.) Jones, R. W. (Brompton Hosp., London SW3 6HP, England). *Proc. R. Soc. Med.* 68(9):593-594; 1975.

The case of a 50-yr-old man in whom an amebic liver abscess appeared 32 yr after an episode of amebic dysentery is presented. The patient presented with a 1-week history of rigors, fever, malaise, anorexia, and generalized aches and pains. The ESR was increased (125 mm/hr), and liver function tests were abnormal. He was treated initially with co-trimoxazole. When his history of amebic dysentery was discovered, a liver scan was performed. A single large space-occupying lesion was seen in the middle of the right lobe. After treatment for 5 days with metronidazole (400 mg, 3 times daily), the ESR fell to 15 mm/hr, the liver function tests returned to normal, and the appearance of the liver scan was improved. His symptoms reappeared, and the feces were found to contain numerous pus cells and some RBC, but no amebae or cysts. After 10 further days of treatment with metronidazole (800 mg, 3 times daily), there was clinical improvement. The author concludes that hepatic amebiasis should be considered as the differential diagnosis in patients who have been in the tropics, even without a past history of dysentery.

6672 HISTOPATHOLOGIC STUDY OF THE LIVER IN THE EARLY CHOLESTATIC PHASE OF ALPHA-1-ANTITRYPSIN DEFICIENCY.

(Eng.) Hadchouel, M.; Gautier, M. (U-56, INSERM, Hopital d'Enfants, Le Kremlin Bicetre, F 94270, France). *J. Pediatr.* 89(2):211-215; 1976.

Liver biopsies obtained during the first 6 months of life from 15 children who had prolonged neonatal cholestasis and alpha-1-antitrypsin deficiency were examined to predict the course of liver damage. The duration of follow-up ranged from 16 months to 19 yr. Liver tissue was obtained by percutaneous needle or by surgical biopsy. Intracellular PAS-positive globules were always observed, even during the first months of life. Their size ranged from 1 to 20 µ, and the number of globules in individual hepatocytes ranged from a single large globule to about 20 small ones. The globules were concentrated in periportal hepatocytes, even in the absence of cirrhosis. Abnormalities in liver cells included cytoplasmic vacuolization, nuclear inclusions, and necrosis. Three morphologic patterns of hepatic alteration were distinguished. The first consisted of six cases with cholestasis, hepatocellular damage, and slight portal fibrosis. The second group comprised five cases with important portal fibrosis and bile duct proliferation. Four cases in which ductular hypoplasia was the main feature formed the third group. A correlation between histologic patterns and clinical course was established. Improvement of liver injury was predicted for group 1, early cirrhosis for group 2, and prolonged cholestasis for group 3. The natural evolution of the alpha-1-antitrypsin deficiency appears to be different in each of the three groups.

6673 TREATMENT OF ASCITES BY REINFUSION OF CONCENTRATED PERITONEAL FLUID--REVIEW OF 318 PROCEDURES IN 210 PATIENTS.

(Eng.) Levy, V. G.; Pauleau, N.; Opolon, P.; Caroli, J. (Hopital St. Antoine, 184 rue du Faubourg, St. Antoine F75012, Paris, France). *Postgrad. Med. J.* 51(598):564-566; 1975.

The results from 210 patients in whom a modified plate dialyzer (Rhone-Poulenc) was used to concentrate ascites for reinfusion are reported. A total of 318 reinfusions were performed. In most cases, the patients had failed to respond to treatment with diuretics. The underlying pathology of the ascites was: alcoholic cirrhosis (155 cases), posthepatic cirrhosis (31), biliary cirrhosis (2), Budd-Chiari syndrome (7), abdominal tumors (7), pancreatitis (1), constrictive pericarditis (1), and miscellaneous (6). In 80 cases, the mean time in which ascites were reduced was 21 hr. The mean weight loss in these cases was 7.34 kg; decrease in abdominal girth, 10.6 cm; and volume of filtrate, 6,570 ml. In 60 cases, the mean increase in plasma volume during reinfusion was 471 ml, but this was transient and returned to basal levels within 10 days. Creatinine clearance also improved transiently from 44 ml/min to 73 ml/min, but usually fell to basal levels within 1 week. The urine volume doubled in 35% of the cases, but a significant natriuresis (>50 mEq/day) was achieved in only 24%. The plasma sodium concentration often fell 7 days after reinfusion. This could be prevented by giving a sodium load during reinfusion; 0.7 mEq/kg was needed to increase the plasma sodium concentration by 1 mEq/l. Of 37 patients with a plasma urea concentration greater than 80 mg/100 ml, only 11 had marked improvement in renal function after the procedure. Pyrexia occurred in 50% of the reinfusions, but disappeared soon afterwards. Pulmonary edema occurred in 12 cases, hemolytic jaundice in 2, and overt gastrointestinal hemorrhage in 11. Peritoneal infection occurred in 14 cases, and this was a major contributing factor to death in 5. The following laboratory changes occurred: decreased platelets (44 patients), decreased fibrinogen (34), decreased factor V (32), decreased factor II or VII + X (18), positive ethanol test (15), and positive Von Kaulla (<2 hr; 5 cases). Of 150 patients, 72 are still alive. The causes of death in the other 78 were liver failure (21), renal failure (21), hepatoma (7), and hemorrhage (15).

6674 CLINICAL EXPERIENCE WITH THE RHONE-POULENC ASCITES REINFUSION APPARATUS.

(Eng.) Arroyo, V.; Mas, A.; Vilardell, F. (Hosp. Clinico y Provincial, Univ. Barcelona, Barcelona, Spain). *Postgrad. Med. J.* 51(598):571-572; 1975.

Results with six patients with cirrhosis and ascites who were treated with the Rhone-Poulenc ascites reinfusion apparatus are presented. Three patients were discharged without ascites after this treatment. Of the remaining patients, one died of acute pulmonary edema, one died from a massive gastrointestinal hemorrhage due to the rupture of an esophageal varix, and the third died from an acute myocardial infarction. There was no differences between the patients who survived and those who died in relation to age, duration of the perfusion, or the amount of ultrafiltrate produced per hour. The infusion of concentrated ascitic fluid was followed by an increase in urine volume and natriuresis in all patients. There was a significant increase in heart rate and central venous pressure in all but one patient. One patient who had not responded to diuretics recovered following the treatment. This procedure could be valuable in the treatment of cirrhotic patients with ascites who cannot be managed by diuretic therapy.

6675 HEPATIC PORTOENTEROSTOMY: INDICATED OR NOT IN THE TREATMENT OF BILIARY ATRESIA?

(Eng.) Campbell, D. P. (Oklahoma Children's Memorial Hosp., P.O. Box 26901, Oklahoma City, OK 73190). *Am. J. Dis. Child.* 129(12):1427-1428; 1975.

Experience with hepatic portoenterostomy in the treatment of biliary atresia is reviewed and discussed. In Japan, the use of hepatic portoenterostomy in the surgical treatment of uncorrectable types of biliary atresia was first reported in 1957, and the cure rate was approximately 10%. More recent reports claim cure rates of 40-50%, using modifications of this procedure. The author has previously performed 13 such procedures, and only three patients have survived. These results cannot be compared with the favorable results reported by the Japanese investigators; it is believed that the Japanese were actually operating on infants with microscopic bile ducts present in the porta hepatis (a form of biliary hypoplasia). Serum lipoprotein-X (LP-X) determinations before and after a short course of cholestyramine resin enable infants with biliary hypoplasia to be eliminated from consideration for surgery; infants with true biliary atresia will show a progressive rise in the serum LP-X level, despite cholestyramine resin administration. Despite the poor results obtained with this procedure, hepatic portoenterostomy is recommended for all infants without grossly identifiable ducts in the porta hepatis; the operation may help if microscopic extrahepatic bile ducts are present. If an infant is to benefit from this procedure, it must be performed before 3 months of age.

6676 BILE ACID METABOLISM IN CHOLESTASIS.

(Ger.) Back, P. (Med. Univ.-Klinik, Freiburg, W. Germany). *Verh. Dtsch. Ges. Inn. Med.* 80: 415-418; 1974.

Some problems in the relation of bile acids to cholestasis (CH) are reviewed. In human CH syndrome, glucuronide formation and sulfate esterification are more effectively prophylactic against possible toxic effects of bile acids than hydroxylation mechanisms. Introduction of a sulfate ester group elicits a 2.4-2.9% greater renal clearance than glycine or taurine conjugates. The effect of differential hydroxylation in the conjugated group is not significant, but in the group of sulfate ester derivatives, it is highly significant ($p<0.001$) between 3β-hydroxy-5-cholenic and cholic acids. No difference obtains between the clearance of sulfate esters of 3β-hydroxy-5-cholenic acid and conjugated bile acids, which suggests that the delay time of this compound is also prolonged in CH. In one case of chronic intrahepatic CH that was refractory to therapy for 2 yr, phenobarbital administration elicited increased formation of cholic glucuronide, which probably represents the effective therapeutic mechanism. CH, neonatal CH, benign and recurrent pediatric CH, the CH of pregnancy and oral contraception, and primary gynecological biliary cirrhosis are all probably expressions of deficient bile acid glucuronidation. This is related to the appearence of atypical, planar bile acids in urine and plasma.

6677 DIFFERENTIAL DIAGNOSIS AND FOLLOW-UP STUDIES IN NEONATES AND INFANTS WITH PERSISTENT CHOLESTASIS. (Ger.) Gathmann, H. A.; Osswald, P.; Muller, G. (Pathologisches Institut, Universitat Erlangen-Nurnberg, D-8520 Erlangen, Krankenhausstrasse 8-10, W. Germany). *Z. Kinderheilkd.* 120(4): 259-276; 1975.

Liver histopathology is reviewed and discussed from differential diagnostic and prognostic perspectives in the long-term management of pediatric cholestases (CHT). Intrahepatic CHT with intrahepatic hypoplasia (11 cases), CHT with overproliferation of intrahepatic ductal segments and intact extrahepatic ducts (1 case), CHT with occluded extrahepatic ducts and intrahepatic ductal proliferation (14 cases), extrahepatic occlusion with intrahepatic hypoplasia (4 cases), intrahepatic CHT with primary inflammation with (10 cases) or without (13 cases) giant cells, and idiopathic intrahepatic CHT (9 cases) comprise the pathogenetic taxonomy of ductal dysplasia. The basic criteria were bile pigment localization, presence of inter- or intralobular duct type, hepatocyte modification, giant cell formation, necrosis, fibrosis, and inflammatory infiltration of portal fields. The question of distinguishing between primary inflammation and congenital malformation is discussed.

6678 CYSTIC DILATION OF THE INTRAHEPATIC BILE DUCTS. (Eng.) Faerber, E. N.; Couper-Smith, J.; Solomon, A. (Baragwanath Hosp., Johannesburg, South Africa). *S. Afr. Med. J.* 49 (32):1303-1304; 1975.

The cases of two black patients with cystic dilatation of the intrahepatic biliary tree are presented. Neither patient had gallstones. In the first patient, a 35-yr-old woman, the serum bilirubin was less than 1.0 mg/100 ml. The second patient, a 68-yr-old woman, had a serum bilirubin level of 8.0 mg/100 ml, mild derangement of liver function, and a palpable liver. The bilirubin level decreased to 1.6 mg/100 ml after she was discharged. The cystic dilatation was detected in both patients by i.v. cholangiography.

6679 THE CLINICAL PICTURE OF ARTERIOHEPATIC DYSPLASIA. (Ger.) Oldigs, H. D.; Muller-Wiefel, D.-E. (Abtlg. Allgem. Padiatrie, Zentrum Kons. Med. II der Universitat, Frobelstr. 15-17, D-2300 Kiel, W. Germany). *Monatsschr. Kinderheilkd.* 124(5):382-383; 1976.

The case history of "arteriohepatic dysplasia" in a 4-yr-old girl is described, and the significance of the syndrome in the differential diagnosis of neonatal cholestasis is discussed. Early postnatal icterus, weight loss, holosystolic noise, moderately elevated SGOT and SGPT, high gamma-glutamyl transpeptidase, and increased direct and total bilirubin comprised the abnormal profile. Exploratory laparotomy found an unremarkable gallbladder and cystic duct, but a hypoplastic ductus hepaticus and ductus choledochus. Intrahepatic bile ducts with cholestasis were confirmed histologically. Biopsy at 8 months found ductule proliferation as an expression of partial extrahepatic bile duct malformation. At 3.5 yr, bile duct hypoplasia and pulmonary artery hypoplasia and stenosis were marked. Enostosis of the left proximal femur was the only skeletal anomaly. The child's weight, height, and intelligence quotient were subnormal. A sibling had died at 3 months with extra- and intrahepatic ductal atresia; two other siblings are normal. This is the first report of arteriohepatic dysplastic syndrome in the German literature.

6680 MARKED ENLARGEMENT OF THE LEFT LOBE OF THE LIVER CAUSING A FALSE-POSITIVE SPLEEN IMAGE. (Eng.) Chaudhuri, T. K.; Bobbitt, J. V. (Veterans Admin. Center, Hampton, VA 23667). *Radiology* 119(1):169-170; 1976.

Experience with 10 patients with markedly enlarged left liver lobes whose posterior (prone) views (^{99m}Tc-sulfur colloid) revealed false-positive splenic defects are reviewed. In one case, the defect was also apparent in the anterior view. In all but one case, this pseudodefect was not present in the posterior image obtained standing up. In this patient, both a ^{131}I-rose bengal liver image and a ^{51}Cr-RBC (heat-denatured) spleen image were obtained for correct interpretation of the splenic defect. The spleen was normal, and the area of uptake above the spleen was a result of the horizontally enlarged left liver lobe. The authors caution against diagnosis from an apparently abnormal posterior image, unless proved by other measures.

6681 THE CYTOTOXICITY OF PLASMA FROM PATIENTS WITH ACUTE HEPATIC FAILURE TO ISOLATED RABBIT HEPATOCYTES. (Eng.) Hughes, R. D.; Cochrane, A. M. G.; Thomson, A. D.; Murray-Lyon, I. M.; Williams, R. (King's Coll. Hosp. Medical Sch., Denmark Hill, London, SE5 England). *Br. J. Exp. Pathol.* 57(3):348-353; 1976.

The cytotoxicity of plasma from patients with acute hepatic failure and the effects of charcoal hemoperfusion on it were studied in cultured hepatocytes from New Zealand white rabbits. Peripheral venous blood was taken from 18 normal subjects, 20 patients with chronic active hepatitis, 13 with extrahepatic biliary obstruction, and 10 with uncomplicated viral hepatitis. Arterial blood samples were taken from 6 patients without liver disease and from 14 patients with fulminant hepatic failure (FHF) undergoing charcoal hemoperfusion treatment. Plasma was separated from the samples, diluted, and one drop of each was added to microculture plates containing the rabbit hepatocytes. There was no significant difference in values for arterial samples from the patients without liver disease and venous samples from the normal controls. The highest cytotoxicity values were from patients with FHF (34 ± 7.56%), followed by viral hepatitis (16 ± 4.25%). Both values were significantly greater than those of control subjects ($p<0.005$ and $p<0.05$, resp.).

Cytotoxicity of plasma from obstructive jaundice and chronic active hepatitis patients did not differ significantly from control values. In the FHF patients treated by charcoal hemoperfusion, the cytotoxicity of arterial samples was significantly higher ($p<0.02$) than that of the venous samples. By heating the samples, a significant reduction in cytotoxicity in both the FHF and viral hepatitis patients occurred. The cytotoxicity of plasma from six FHF patients showed no significant difference before and after millipore filtration. When plasma from two of these patients was dialyzed against buffer, cytotoxicity decreased from 51% to 4% and from 65% to 21%, resp. The addition of a variety of substances to plasma, including bile acids and bilirubin, enhanced cytotoxicity, but only to a significant degree with lithocholic and chenodeoxycholic acids (44%, $p<0.005$ and 54%, $p<0.001$, resp.). The results suggest that the cytotoxicity in patients with liver disease may be related to substances found in the plasma during liver necrosis, and that bilirubin is not implicated.

6682 CHOLANGITIS COMPLICATING CONGENITAL HEPATIC FIBROSIS.

(Eng.) Howlett, S. A.; Shulman, S. T.; Ayoub, E. M.; Alexander, R. A.; Donnelly, W. H.; Cerda, J. J. (Univ. Florida Coll. Medicine, Gainesville, FL 32610). *Am. J. Dig. Dis.* 20(8):790-795; 1975.

The case of a 5.5-month-old girl who survived cholangitis complicating congenital hepatic fibrosis is presented. The patient was hospitalized with a 16-day history of fever. The liver and spleen were palpable. At exploratory laparotomy, the liver was diffusely mottled, with a whitish reticular appearance. No evidence of collateral portal venous circulation was seen, and the spleen appeared normal. Operative wedge and needle liver biopsies confirmed the diagnosis of congenital hepatic fibrosis and acute suppurative cholangitis. Polymorphonuclear leukocytes were seen around and within the bile ducts and had infiltrated the bile duct endothelium. Although bacteria were observed within these leukocytes by electron microscopy, the surgical specimen was not cultured. *Klebsiella aerogenes* was isolated from the blood cultures. The patient remained afebrile during a 2-week course of i.v. gentamycin. Subsequently, the fever recurred in spite of p.o. cephalexin. Because of persistent anemia, she was transfused with 75 ml of packed RBC in preparation for a percutaneous needle-liver biopsy, which was performed immediately afterward. The liver biopsy was unchanged, and cultures of the homogenate grew *K. aerogenes*. The patient rapidly became afebrile without antibiotic therapy. She has had no signs of infection for the past 12 months, although hepatomegaly persists. The recovery of the patient at a time when she was febrile, had positive cultures, but was not on antibiotics could be due to the spontaneous resolution of a partial intrahepatic biliary obstruction, a response to the blood transfusion, or to the possibility that the febrile illness was unrelated to the positive liver biopsy culture. These possibilities all suggest that a conservative approach to this situation be considered.

6683 CHOLANGIOCARCINOMA ARISING IN CONGENITAL HEPATIC FIBROSIS: A CASE REPORT.

(Eng.) Daroca, P. J., Jr.; Tuthill, R.; Reed, R. J. (Tulane Univ. Sch. Medicine, 1430 Tulane Ave., New Orleans, LA 70112). *Arch. Pathol.* 99(11):592-595; 1975.

The case of a patient with cholangiocarcinoma arising in congenital hepatic fibrosis is presented, together with the gross necropsy findings and the histologic findings in biopsy and autopsy specimens. The patient, a 62-yr-old woman, presented with progressive weakness, weight loss, pain in the right shoulder and back, and cough. Twenty years previously, a cholecystectomy and liver biopsy had been performed after a diagnosis of chronic cholecystitis had been made. Abnormal laboratory values included the following: serum alkaline phosphatase (115 mU/ml), serum bilirubin (1.2 mg/100 ml), and serum albumin (2.4 g/100 ml). An x-ray series disclosed esophageal varices, and a ^{49m}Tc sulfur colloid liver scan was interpreted as an abnormal pattern, indicative of cirrhosis with portal hypertension. The patient died after a period of acute distress and diaphoresis. At autopsy, signs of portal hypertension, congestive splenomegaly (600 g), and hepatomegaly (1,600 g) were observed). The cut surface of the liver showed irregular, glistening fibrous trabeculae. An irregularly outlined, gray-white tumor measuring 5 cm in diameter was present within the right lobe of the liver near the porta hepatis. Metastatic tumor was present in both adrenal glands, in lymph nodes of the porta hepatis, and in both lungs. Tumor nodules were found on the cortical surface of the kidney and the apical interventricular septum. Sections of the liver from the biopsy and autopsy specimens were similar, except for more extensive fibrosis on the latter. Microscopically, the portal trabeculae were characterized by hyperplasia and distortion of bile ductules. Some of the ductules contained inspissated bile thrombi. In many areas, the bile ductules extended from the portal trabeculae through the periportal limiting plate, entered the periphery of the hepatic lobule, and appeared to become contiguous with liver cell cords. The pattern of the neoplasm was that of an adenocarcinoma of bile duct origin, but it varied in the degree of differentiation. In some areas, it was well differentiated, mimicking the "picket fence" character of bile duct epithelium. In other areas, the tumor was poorly differentiated, assuming the pattern of a giant cell carcinoma.

6684 INCREASED SERUM URATE IN GALACTOSEMIA PATIENTS AFTER A GALACTOSE LOAD: A POSSIBLE ROLE OF NUCLEOTIDE DEFICIENCY IN GALACTOSEMIC LIVER INJURY.

(Eng.) Forster, J.; Schuchmann, L.; Hans, Ch.; Niederhoff, H.; Kunzer, W.; Keppler, D. (Biochemisches Institut der Universitat, D-7800 Freiburg i. Brsg., Hermann-Herder-Str. 7, W. Germany). *Klin. Wochenschr.* 53(24):1169-1170; 1975.

The effects of a p.o. load of galactose under standardized conditions were studied in five galactosemic and five normal children. The maximal blood galactose level after 1.5 hr was 12.6 ± 2.0 mM in children with a deficiency of uridylyl transferase and 5.8 ± 1.2 mM in the controls. The concentration of serum urate in galactosemics increased to 155% of the fasting level ($p<0.005$); no rise was detectable in the controls. The elimination of urate with the urine was augmented by the same amount in both groups. These studies provide evidence for an increased catabolism of hepatic nucleotides, which may lead to a deficiency of nucleotides, has been proposed as a cause of galactosemic liver injury.

6685 CONTINUOUS NOCTURNAL INTRAGASTRIC FEEDING FOR MANAGEMENT OF TYPE I GLYCOGEN-STORAGE DISEASE.

(Eng.) Greene, H. L.; Slonim, A. E.; O'Neill, J. A., Jr.; Burr, I. M. (Vanderbilt Univ. Sch. Medicine, Nashville, TN 37203). *N. Engl. J. Med.* 294(8):423-425; 1976.

A study was carried out to determine whether continuous nocturnal intragastric feeding, combined with frequent daytime feedings, would represent a practical long-term medical alternative to portacaval shunting in patients with type 1 glycogen-storage disease. In addition, the efficacy of using clofibrate as an adjunct to such therapy was investigated. Three patients with type 1 disease were treated with intragastric infusions of a high glucose formula at night and 3-hr starch feedings during the day. This regimen stabilized blood glucose levels above 70 mg per deciliter and decreased serum uric acid, triglyceride, lactate and serum oxalacetic transaminase levels, as well as hepatic size, in all patients. Increased linear growth rate (mean of 1 cm/month) was associated with a decrease in mean plasma glucagon (from 190 to 40 pg/ml) and an increase in mean plasma insulin [from 19 to 43 μU/ml, (two patients)]. These changes occurred within 4 weeks of treatment and continued with home treatment for 13 months. No complications resulted from tube placement daily by the patients. One patient received clofibrate (50 mg/kg) daily in two divided doses. The metabolic responses in this patient were similar to those obtained during nocturnal feeding, with the exception that blood glucose levels were lower (80 mg/dl during treatment with clofibrate and 99 mg/dl during treatment with nocturnal infusions). In the other two patients, the blood glucose levels were 96-111 mg/dl. The results indicate that type 1 disease can be managed by nighttime intragastric feeding and frequent daytime high starch meals.

6686 PELIOSIS HEPATIS IN AN INFANT.

(Eng.) Nuernberger, S. P.; Ramos, C. V. (St. Louis Univ. Sch. Medicine, 1402 S. Grand St., St. Louis, MO 63104). *J. Pediatr.* 87(3):424-426; 1975.

The case of a 15-month-old girl with peliosis hepatis is presented. The child had a 2-day history of vomiting and fever. The liver edge was tender and located 5 cm below the right costal margin. The patient died 18 hr after hospitalization. The postmortem findings included 750 ml of serosanguineous fluid within the thoracic cavity, bilateral pulmonary congestion, focally ulcerated bladder mucosa, and a friable liver with a nodular gray-brown mottled surface. Histologically, the liver contained multiple vascular lakes, without evidence of a fibrous or endothelial lining, red cell margination, or thrombi. These vascular lakes were located throughout the lobules and did not usually communicate with the central veins. Kidney sections revealed evidence of early pyelonephritis. This patient appears to be the youngest recorded case of peliosis hepatis.

6687 CHOLESTEROL POLYCORIA IN THE ADULT: CLINICAL AND HISTOCHEMICAL ASPECTS.

(Fre.) Lageron, A.; Lichtenstein, H.; Bodin, F.; Conte, M. (U9, INSERM, Hopital Saint-Antoine, 75012 Paris, France). *Med. Chir. Dig.* 4(1):9-14; 1975.

A case is reported of cholesterol ester storage disease (cholesterol polycoria) in a 45-yr-old woman. The clinical picture was dominated by hepatomegaly. The liver was extremely large, firm to palpation, and laparoscopy revealed a homogeneous, slightly granulated surface of a "butter yellow" color. The hepatomegaly was accompanied by signs of portal hypertension including radiologically evident esophageal varices. Hepatic scintigraphy with ^{198}Au showed homogeneous distribution of the isotope with hypofixation at the junction of the right and left lobes. No anomalies of arteries or veins were observed on arteriography. The only abnormal value obtained in a complete liver function study was serum hyperlipemia (total lipids were 13 g/l; cholesterol was 3 g/l). Radiological examination of the biliary tract and all other examinations were negative. The hyperlipemia did not respond to treatment with cholestyramine. The disease had a very long evolution, 36 yr, during that time the patient was hospitalized on several occasions for a pseudo-angiocholitis. The genetic character of the disorder is indicated by the presence of the symptoms in the patient's 20-yr-old son. The case is the sixth reported in the literature. Final diagnosis of the disorder depends on the spongy appearance of the hepatocytes due to the presence of an excess of esterified cholesterol.

6688 REYE'S SYNDROME WITHOUT FATTY LIVER.

(Eng.) Gosseye, S.; De Meyer, R.; Maldague, P. (Clinique Universitaires Saint-Raphael, Capucijnenvoer 35, 3000 Leuven, Belgium). *Helv. Paediatr. Acta* 30(6):509-513; 1975.

The case of a 2.5-yr-old boy who developed a fatal case of Reye's syndrome without fatty liver is presented. The patient was hospitalized with symptoms typical of Reye's syndrome, i.e., vomiting, fever, coma, and hyperammonemia (360 μg/100 ml). The patient was also slightly icteric, and the total bilirubin level was 5.35 mg/100 ml. The liver was palpable. Despite treatment with glucose, electrolyte, and bicarbonate perfusions, the blood ammonia level rose to 753 μg/100 ml. Temporary improvement occurred after an exchange transfusion, but the patient again became comatose and died from cardiac arrest. The postmortem examination revealed that the liver was grossly normal, except for congestion. Sections stained with Oil Red O showed only tiny fat droplets, loosely scattered in the liver cells. It appears that the classical, massive, and diffuse fatty degeneration of the liver is not an essential feature of Reye's syndrome.

6689 INTRAHEPATIC STONES. (Eng.) Mosavy, S. H.; Saghafi, M. R.; Moinedin, Kh. (No affiliation given). *Abdom. Surg.* 17(10):223-224; 1975.

The cases of two patients with intrahepatic stones are presented. The first patient, a 53-yr-old woman, presented with icterus, hepatosplenomegaly, and upper right quadrant pain. Twenty-four hours after hospitalization, she developed massive hemorrhage from esophageal varices and died. At autopsy, the liver was congested and enlarged (1,400 g) and contained intrahepatic stones ranging from 2 to 5 cm in diameter. The gallbladder was 6 x 4 x 2 cm and contained 10 ml of concentrated bile. The stones had caused biliary cirrhosis. The second patient, a 40-yr-old woman with a history of cholecystitis, presented with abdominal pain, vomiting, and a palpable liver. I.v. cholangiograms showed dilatation of the common bile duct and right hepatic duct. Some radiopaque shadows were interpreted as intrahepatic stones. This was confirmed at surgery, and three stones were removed by transhepatic lithotomy. The gallbladder was normal, but two stones were removed from the common bile duct. In both cases, the diagnostic procedure of choice for intrahepatic stones is percutaneous transhepatic cholangiography.

6690 STUDIES RELATIVE TO THE RADIOSENSITIVITY OF MAN: BASED ON RETROSPECTIVE EVALUATIONS OF THERAPEUTIC AND ACCIDENTAL TOTAL-BODY IRRADIATION. (Eng.) Ricks, R. C.; Lushbaugh, C. C. (Oak Ridge Associated Univ., TN). 226 pp.; 1975 [available through National Technical Information Services, Washington, DC; Document No. N75-32733/8WJ].

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

6709 HISTOENZYMOLOGICAL, HISTOCHEMICAL, AND ULTRASTRUCTURAL STUDY OF A CASE OF DUBIN-JOHNSON SYNDROME. (Fre.) Chamlian, A.; Casanova, P.; Remacle, J.-P.; Mathieu, B.; Laffargue, P. (Centre Hospitalier Universitaire Timone, chemin de l'Armee-d'Afrique, 13385 Marseille Cedex 4, France). *Arch. Anat. Pathol.* 24(1):7-12; 1976

The case of a 48-yr-old woman with Dubin-Johnson syndrome (chronic idiopathic jaundice) is reported. Histoenzymological and ultrastructural studies of the liver showed pigment granulations made up of lipomelamines accumulated in the lysosomes. Acid hydrolase (acid phosphatase, beta-glucuronidase, and sulfatase) enzymatic activities of the granules were most apparent in the pericentrolobular hepatocytes and suggested the existence of a hepatic deconjugation process. The lobular distribution of the mitochondrial dehydrogenases was not modified. However, glucose-6-phosphatase dehydrogenase was very low in all cells of the hepatic lobule. As previously reported in the literature, there were no specific enzymatic anomalies at the level of the hepatocytes or of the bile ducts, and thus, it is impossible to determine the mechanism of the excretory disorder or that of the pigment retention in the lysosomes.

6710 CLINICAL EXPERIENCE WITH THE USE OF PHENOBARBITAL FOR HYPERBILIRUBINEMIA PROPHYLAXIS IN FULL-TERM BABIES. A CONTROLLED STUDY. (Ger.) Schambach, K.; Menzel, K. (Kinderklinik, Medizinische Akademie, 50 Erfurt, Am Schwemmbach 32a, E. Germany). *Z. Aerztl. Fortbild. (Jena)* 69(10):535-537; 1975.

The effectiveness of phenobarbital as an enzyme inducer in hyperbilirubinemia prophylaxis was tested in 958 alternately treated, clinically healthy, term neonates without blood group incompatibility. The infants received the equivalent of 5 or 10 mg/kg/day phenobarbital on postnatal days 1-3, and the serum bilirubin was assayed spectrophotometrically on day 4. Serum bilirubin decreased from a median of 5.00 mg/100 ml in the control group (154 infants) to 4.52 mg/100 ml in the 5-mg group (161 infants). Serum bilirubin decreased with the 10-mg dose infants from 5.02 mg/100 ml in the controls (314 infants) to 4.03 mg/100 ml in the experimental group (329 infants), $p<0.01$. The frequency distribution found most of the serum bilirubin levels in all groups clustered between 2 mg/100 ml and 9.9 mg/100 ml. Values above 12 mg/100 ml confirmed the clinical role of phenobarbital. A serum bilirubin level of 15 mg/100 ml was found in 11 untreated cases, all of which required exchange transfusions for hyperbilirubinemia, while serum bilirubin levels were effectively controlled by 10 mg/kg phenobarbital in all cases. The strongest phenobarbital effect occurred in infants with a birth weight over 3,000 g, a gestation age of 40 or more weeks, and ABO- and Rh-congruent blood group patterns. Side effects were confined to slight sedation after 10 mg/kg phenobarbital. With a high risk of bilirubin encephalopathy, phenobarbital is the management of choice.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

6713 LIVER CHANGES IN BURNS, AS SEEN IN THE CLINICAL MORPHOLOGIC PICTURE. (Eng.) Chlumsky, J.; Dobias, J.; Vrabec, R.; Marecek, B.; Chlumska, A.; Matejicek, V. (Medical Faculty Hygiene, Charles Univ., Prague, Czechoslovakia). *Acta Hepatogastroenterol. (Stuttg.)* 23(2):118-124; 1976.

Changes observed in the livers of 30 patients who survived severe burns are reported. In the shock period (immediately after the injury), serum transaminases were elevated in only two patients. Histologically, the Kupffer's cells were slightly activated, there were enlarged hepatocyte nuclei, and focal steatosis was present. SGOT and SGPT levels were increased (up to 170 mU/ml and 210 mU/ml, resp.) during the septic stage (from the end of the first week). The serum bilirubin level was also slightly higher (to a maximum of 5 mg%). At this time, the liver was slightly enlarged and sensitive. Light microscopy revealed focal steatosis in the hepatocytes, and the extent was directly proportional to the duration of sepsis. Focal necrosis was noted in two cases. Hepatic tissues were examined by electron microscopy in 15 cases at various intervals (1 month to 3 yr after the injury). At 1-8 months, the smooth endoplasmic reticulum was focally dilated, and glycogen was absent or present in reduced amounts. The microvillous surfaces of hepatocytes showed regressive changes. Bile retention within the hepatocytes was common. A striking feature in the livers of patients requiring prolonged treatment was that the smooth endoplasmic reticulum remained widened and increased, even in samples taken long after injury. Hepatocytes with two nuclei were often present. Regressive changes in the Kupffer's cells were found at all stages. There was no direct relation between the liver changes and the patients' ages, either during the shock period or the septic period.

6714 JAUNDICE AFTER APRINDINE. A HEPATITIS-LIKE HEPATIC DAMAGE. (Ger.) Brandes, J.-W.; Schmitz-Moormann, P.; Lehmann, F.-G.; Martini, G. A. (Medizinische Universitatsklinik, 3550 Marburg, Munnkopffstr. 1, W. Germany). *Dtsch. Med. Wochenschr.* 101(4):111-113; 1976.

The case history of hepatotoxic sequelae in a 50-yr-old woman under aprindine (APR) management for cardiac arrhythmia is reported. After a 7-yr history of procainamide and digitalis for arrhythmia and Briserin for hypertension, the patient was switched to APR. Nausea, anorexia, headache, constipation, and pressure sensation in the right hypochondriac region set in 8 days later. Within 2 weeks, findings of elevated serum transaminases, alkaline phosphatase, and bilirubin suggested viral hepatitis, although B-antigen was not demonstrable. Leucine aminopeptidase, gamma-glutamyl transpeptidase, LDH, serum amylase, and urinary amylase were also increased. All other paraclinical findings were negative, including the absence of eosinophilia. Concurrent liver histology found dilated portal fields, Councilman's bodies in the parenchyma, sporadic necrosis, moderate hepatocyte polymorphy, and a surprising number of hepatocyte mitoses. Normalization of clinical and paraclinical signs, including reduction of the hepatomegaly, followed cessation of APR. A trial resumption of APR for 3 days led to a renewal of the previous signs and symptoms within 24 hr, with complete normalization 10 days after total cessation of the drug. The findings are compatible with a diagnosis of drug-induced hepatitis.

6715 GRANULOMATOUS CONDITION OF THE LIVER PRODUCED BY PHENYLBUTAZONE. (Dan.) Anker, N.; Skovbjerg, H. (Fjordparken 10, DK-4000 Roskilde, Denmark). *Ugeskr. Laeger* 137(51):3038-3039; 1975.

A case of liver granuloma occurring after treatment with phenylbutazone is described. The patient was a 58-yr-old woman with no known allergic sensitivities. Treatment for a prior zoster condition had included phenylbutazone (300 mg daily for 3 weeks, for a total of 5.8 g). Icterus and erythema followed, together with indigestion, discoloration of stools, fever, and edema of the hands and feet. There was no reason to suspect either serum or infectious hepatitis. Most clinical tests showed negative results, but a liver biopsy revealed a granulomatous condition in the parenchyma and hepatic portal, with eosinophilia. No other abnormalities were observed. All symptoms disappeared within 14 days of cessation of treatment with phenylbutazone, and a liver biopsy taken 6 months later was normal. The granuloma appears to have been a hypersensitive reaction to phenylbutazone.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

6720 THE PREVENTION OF VIRAL HEPATITIS. (Eng.) Krugman, S. (New York Univ. Medical Center, 550 First Ave., New York, NY 10016). *Ann. Clin. Res.* 8(3):216-220; 1976.

The epidemiology of hepatitis A virus and hepatitis B virus and the prevention of infection by these viruses are reviewed. The type A virus is spread from person to person via the fecal-oral route during the end of the incubation period and for about two weeks after onset of the symptoms. There is no carrier state. Besides physical contact, the disease is spread via food, milk, and water. Passive immunization can be effected with standard human immune globulin (ISG), and is recommended for those who have had intimate exposure to the disease. Active immunization has not yet been developed and is contingent on the successful cultivation of the virus *in vitro*. The type B virus is usually transmitted parenterally via contaminated blood, blood products, and needles. It may also be transmitted via intimate personal contact, particularly in areas with primitive sanitary conditions. Blood for transfusion from commercial donors has a 10- to 15-fold greater risk of carrying infection than blood from volunteers. Equipment, if reused, should be boiled for 10 min or autoclaved at 15 lbs pressure or by dry heat at 338 F for 30 min. The efficacy of ISG for prevention of type B infection depends on the amount of protective antibody in the particular preparation and on the dose of virus transmitted during exposure. Studies with a high titer hepatitis B ISG preparation showed a significant protective effect. It is recommended that either hepatitis B ISG or standard ISG be given to infants exposed *in utero* or at birth. Evidence has shown that heat-inactivated serum has a protective effect as an active immunizing agent. The results indicate the feasibility of developing a vaccine using purified HBsAg, in spite of the fact that the virus has not been isolated in cell culture.

6721 PREVENTION OF NOSOCOMIAL VIRAL HEPATITIS, TYPE B (HEPATITIS B). (Eng.) Snydman, D. R.; Bryan, J. A.; Dixon, R. E. (Center Disease Control, Atlanta, GA 30333). *Ann. Intern. Med.* 83(6):838-845; 1975.

Measures for preventing nosocomial viral hepatitis B are outlined. The keystone of an effective hepatitis control program in the hospital is the adequate surveillance of patients and personnel, especially in high-risk areas such as dialysis units, hematology-oncology units, and clinical pathology laboratories. Other preventive measures include good personal hygiene, avoiding habits that favor the transmission of the disease (nail biting, putting hands in the mouth, and chewing on various objects), the provision of adequate washing facilities, the sterilization and disinfection of instruments and equipment, and the use of protective clothing. Individuals with well-defined histories of inoculation or exposure to known hepatitis B surface antigen (HBsAg)-positive blood or fluids (accidental needle punctures or accidental ingestion) may benefit from the administration of standard immune globulin of recent manufacture (0.04-0.10 ml/kg) after the institution of prompt local measures (thorough washing of the exposed area). Data currently available suggest that employees who have persisting HBsAg need not be removed from their positions unless they have been shown to disseminate infection. If HBsAg persists for 6 months or longer, liver function and histologic data should be evaluated for chronic active hepatitis.

6722 THE PROGRAM OF THE WORLD HEALTH ORGANIZATION IN THE INTERNATIONAL SURVEILLANCE OF VIRAL HEPATITIS B. (Eng.) Sobeslavsky, O. (Virus Diseases Unit, World Health Organization, Geneva Switzerland). *Am. J. Med. Sci.* 270(2):283-285; 1975.

The epidemiology of hepatitis B in different areas of the world is being studied by the World Health Organization. The first phase of the study consisted of evaluation of antiserum to hepatitis B surface antigen (anti-HBsAg). The serum has been approved for use as a reference reagent by the National Institutes of Health and contains antibody to the D and Y subtypes. Collaborating laboratories in 27 countries titrated this serum against their own locally available serum controls. A high degree of specificity and sensitivity was shown uniformly for the reagent sera. A second phase of the study is now in progress and is concerned with defining the prevalence of hepatitis B antigen and antibody in the general populations and with identifying high-risk groups. Collected sera would be tested for antibody by discontinuous counter-immunoelectrophoresis using the anti-HBs reagent and by reverse passive hemagglutination. It is suggested that prospective studies of transfused patients could aid in assessing the kinetics and specificity of antibodies to different hepatitis B antigen components.

6723 TREATMENT OF ACUTE VIRAL HEPATITIS WITH LEVULOSE INFUSIONS. (Ger.) Bode, J. Ch.; Bungartz, G.; Dolle, W. (Medizinische Universitatsklinik, 355 Marburg, Mannkopffstr. 1, W. Germany). *Dtsch. Med. Wochenschr.* 101(2):43-47; 1976.

Experiences with fructose management of acute hepatitis in 109 patients (group A) are compared with those in 91 hepatitis patients (group B) without fructose. Both groups were similar in age composition and number of patients receiving glucocorticoids, calorie-rich, light diets, and bed-rest. Group A received an average 900 ml (500-2,000 ml, i.v.) of a 59% fructose solution daily for the first 3 weeks. Serum transaminase and bilirubin were monitored for 40 days after the onset of therapy. Differences between groups A and B were negligible for 15 days after the onset of icterus. After day 20, the average bilirubin concentration was significantly higher ($p<0.01$) in group A. The typical spontaneous fall in bilirubin concentration 3 weeks after the onset of icterus was postponed for 1 week in group A. Only in the seventh week were the average values for both groups approximately equal. The group difference in SGPT decline was insignificant, with the slope of the curves approximately the same; group A values were slightly higher throughout the decline. The average duration of illness was a function of age in both groups, with a somewhat shorter duration for group B patients in most age classes. Compatible with a survey of relevant literature, fructose infusion confers no therapeutic advantage.

6724 PROBLEMS OF HEPATITIS IN DIALYSIS PATIENTS, THE SUPPORT STAFF AND THEIR RELATIONS. (Ger.) Schirmer, K.; Sohn, U.; Hajduk, F.; Woratz, G.; Zimmermann, S.; Agsten, E.; Schreiber, M. (Klinikum am Kuchwald, 90 Karl-Marx-Stadt, E. Germany). *Z. Gesamte Inn. Med.* 30(17):579-582; 1975.

The incidence of hepatitis in dialysis patients and in the support staff and their relations was reviewed during a 2-yr monitoring period. The risk group consisted of 14 patients, 12 nurses, and 5 physicians. Australia antigen (Au Ag) was detected in nine patients, two nurses, and two family members (of one nurse and one patient). The four affected members of the nonpatient group presented with frank icterus and elevated serum bilirubin (maximum 21 mg/100 ml). Bilirubin elevations were infrequent in patients. Serum transaminases in nonpatients were markedly increased (over 800 IU), but were only moderately elevated in all Au Ag-positive patients (maximum SGOT, 120 IU; SGPT, 180 IU). The general status of the nine affected patients was poor. The interval between Au Ag demonstration and the onset of serum transaminase elevation varied in patients from several days to 6 weeks; excepting two patients, Au Ag levels remained constant, while serum transaminase was normalized after several weeks. The two patients with waning Au Ag had prominent right heart insufficiency. The patients received no corticoid or immunosuppressive therapy before or during dialysis. In nonpatients, the extinction of Au Ag levels followed serum transaminase normalization. Au antibodies were found in one patient and one nonpatient who had had a hepatitis infection 8 yr previously. Isolation and disinfection procedures in affected dialysis clinics are discussed.

6725 PHYSIOPATHOLOGY OF HEPATITIS B VIRUS INFECTION.

(Fre.) Guignard, D.; Nydegger, U.; Lambert, P. H.; Miescher, P. A. (Hopital Cantonal, CH-1211 Geneve 4, Switzerland). *Schweiz. Med. Wochenschr.* 105(33):1033-1040; 1975.

Forty-eight of 10,000 blood donors were found to be asymptomatic and hepatitis B associated antigen (HBAg)-positive. Histopathological examination of the liver of 25 revealed abnormal pathology (inflammatory foci, chronic hepatitis, and postnecrotic cirrhosis, etc.) in all but 6 subjects. Thrombocytopenia was present in 17% and bone marrow studies of six of eight carriers with less than 100,000 platelets/mm^3 revealed numerous megakaryocytes and normal morphology. Transaminases, SGOT, and SGPT were moderately elevated (<50 IU/liter) in 20/48 asymptomatic carriers. When carriers were categorized according to subtype of HbAg, 54% exhibited the surface antigen *ad*; 34%, *ay*; and 12%, *ad/ay*. A similar distribution of HbAg subtyping was found in a group of 82 hepatitis B patients. The serum of 31 patients studied for the presence of antigen-antibody complexes (Clq binding test) revealed 11 with detectable levels of the circulating complex; 2/3 patients with HbAg positive polyarteritis nodosa also had circulating antigen-antibody complexes. The Clq binding test was negative in all the asymptomatic HbAg positive blood donors tested. The authors discuss the pathophysiologic implications of hepatitis B infection and conclude that the main defense mechanism leading to elimination of the viruses within the hepatocytes is cell-mediated immunity. Hepatitis would then represent the side reaction of this defense mechanism. Polyarteritis nodosa may result from local antibody interaction with antigen fixed within arterial walls.

6726 DETECTION OF HBsAg AND HBsAb IN SWEAT.

(Eng.) Brodersen, M.; Wirth, M. (Medizinische Univ. Klinik, Luitpoldkrankenhaus, Josef-Schneider-Str. 2, 8700 Wurzburg, W. Germany). *Acta Hepatogastroenterol.* 23(3):194-201; 1976.

HBsAg excretion was studied in the sweat of 18 HBsAg-positive and 20 HBsAg-negative subjects, and HBsAb excretion was studied in 5 HBsAb-positive and 10 HBsAb-negative subjects. The subjects showered and dried, and the sweat was collected during a 45-min application of heat. In the HBsAg study, sweat amounts varied from 11 to 550 ml; the concentration was 7-220-fold. HBsAg was detectable by radioimmunoassay only, and occurred in nine seropositives and no seronegative controls ($p<0.01$). There was no difference between subtype D (7/13) and subtype Y (2/4). The frequency of HBsAg detection in sweat correlated well with serum titer and blood contamination. Sweat HBsAg occurred more often in acute and chronic persisting hepatitis than in cirrhosis. There was a striking difference in the serum titer in these groups (9/10 were immunodiffusion positive in acute and chronic persisting hepatitis, but only 1/5 cirrhotics were). HBsAg sweat occurred at a 10^6-10^7-fold lower concentration than the corresponding serum antigen. Centrifugation in CsCl revealed a density of 1.25 and 1.21 g/cm^3 for sweat and corresponding serum HBsAg. The quantity of sweat in the HBsAb study ranged from 60 to 840 ml; the concentration was 50-560-fold. Quantitation in sweat from the negative subjects was low, with little variation, while in the positive group it was higher and spread over a wide range. The difference between the groups ($p<0.01$) indicates a specific binding of HBsAg in the positive group. There was a striking similarity in quantitation between sweat specimens from the negative group and the negative control serum. Assuming this similarity to be proof of the nonexistence of sweat HBsAb in negative subjects, four of five seropositive subjects had HBsAb in their sweat. Centrifugation showed HBsAb activity in both serum and sweat to be confined to immunoglobulin G (IgG)-containing fractions. Anti-alpha antiserum did not impair activity, but anti-Y activity completely inhibited it. Specific activity was 480 and 437 counts per min/mg IgG for serum and sweat, resp. The results suggest that HBsAg may serve as a marker to calculate infectivity of sweat, compared to the corresponding serum specimen, and that HBsAb in sweat could provide protection against reinfection by contact.

6727 CORE AND SURFACE ANTIGEN OF THE DANE PARTICLE IN LIVER TISSUE: RELATION TO DIFFERENT FORMS OF HEPATITIS B.

(Ger.) Bianchi, L.; Gudat, F. (Institut fur Pathologie, Universitat Basel, Schonheinstrasse 40, CH-4056, Basel, Switzerland). *Leber Magen Darm* 5(5):180-195; 1975.

The differential serological and histological behavior of hepatitis B antigenic components (HBAg) in 67 patients with different types of hepatitis was explored by immunofluorescence (IF) and light and electron microscopy. The patients were divided into two groups. One consisted of 20 renal transplant patients under immunosuppressive (IS) therapy (azathioprine, 0.5-4.0 mg/kg/day; prednisone, 15-300 mg/day; and antilymphocyte globulin) for 2-12 weeks after surgery. There were 5 HBAg-positive and 15 -negative cases. The second group consisted of 47 patients with spontaneous hepatitis; 25 were HBAg-positive and 22 were -negative. In the transplant group, there were 16 cases of nonspecific reactive hepatitis (NRH), 14 of which were negative for hepatitis B core antigen (HBcAg); 3 cases of portal hepatitis (chronic persistent type), 1 of which was negative; and 1 case of periportal hepatitis (active chronic hepatitis) under IS therapy. The involvement of the entire hepatocyte nucleus by HBc was typical of NRH. Every type of hepatitis except subacute hepatic necrosis occurred in the spontaneous hepatitis group. No tissue correlate could be found for 7/25 seropositive cases. Of the 18 positive patients, periportal and lobular types were equally HBc- and HBsAg, while portal, nonspecific reactive, and histo-carrier hepatitis types were predominantly HBsAg. Based on the two groups, four histotypical responses are recognizable: HBc predominance (IS type), elimination type (little or no HBAg), HBc+s equivalence (active type), and HBs predominance (carrier type).

6728 RESULTS OF THE FOLLOW-UP EXAMINATIONS OF AUSTRALIA ANTIGEN-POSITIVE SUBJECTS WITH CONTACT WITH HEPATITIS PATIENTS.

(Ger.) Schulze, B.; Ullmann, R.; Konnecke, M.-L.; Scholtze, K. (Inspektion Kommunalhygiene, Hygiene-Instituts des Bezirkes Erfurt, 50 Erfurt, Predigerstrasse 6, E. Germany). *Z. Aerztl. Fortbild. (Jena)* 70(1):40-42; 1976.

Epidemiological studies of the presence of Australia antigen (AuAg) in 416 persons exposed to hepatitis patients are analyzed. AuAg was positive by complement-fixation in 76, and 146 showed positive enzymatic evidence of hepatitis. Of these, 75 were found to have acute liver involvement, including 59 abortive, 10 anicteric, and 6 icteric hepatitides; 12 were AuAg-positive. AuAg was detectable in 64 subjects who were clinically and paraclinically negative; subsequent examination of 50 of these found 3 with hepatosplenomegaly and 2 with serum lability and dysproteinemia. The implications of "healthy carriers" are discussed.

6729 BIOCHEMICAL CHARACTERIZATION OF AUSTRALIA ANTIGEN: EVIDENCE FOR DEFECTIVE PARTICLES OF HEPATITIS B VIRUS.

(Eng.) Gerin, J. L.; Ford, E. C.; Purcell, R. H. (Molecular Anatomy Program, Oak Ridge Natl. Lab., 5640 Fishers Lane, Rockville, MD 20852). *Am. J. Pathol.* 81(3):651-668; 1975.

The existence of subpopulations of Dane particles obtained from the sera of high-titered asymptomatic carriers of the hepatitis B surface antigen (HBsAg)/*adw* and HBsAg/*ayw* subtypes was demonstrated by the staining properties of the particles' internal cores and by differences in the buoyant densities of these particles in cesium chloride. When 12 *adw* and 12 *ayw* plasma units from chronic HBsAg carriers were examined by immune electron microscopy, no significant differences were observed with regard to subtype in terms of the proportion of units containing either Dane particles (92% for *adw* and 75% for *ayw*) or circulating immune complexes (75% for adw and 67% for *ayw*). Thus, most if not all asymptomatic carriers of HBsAg appear to circulate virions in their sera, regardless of subtype. Electron microscopy revealed that Dane particles could be classified based on the staining properties of their internal cores into those having full cores, partially full cores, or empty cores. Quantitative evaluation of six Dane particle-rich preparations showed that the percentage of Dane particles with full cores ranged from 3.4-13.0%, with an average value of 7.2%; the percentage of particles with empty cores ranged from 2.8-16.5%, with an average value of 8.9%. In contrast, the bulk of these Dane particles (average of 83.9%) contained partially full cores, with the percentage of such particles ranging from 72.2-91.2%. These partially full core-containing particles appeared to be deficient in viral nucleic acid and are postulated to be defective interfering forms of hepatitis B virus. Isopycnic banding of a 20-fold concentrate of Dane particles in cesium chloride revealed two populations of particles at densities of 1.19 and 1.25 g/cm^3, resp.; the demonstration of density subpopulations of Dane particles appears to verify the prediction of this result based on the staining properties of Dane particle cores. The bulk of the Dane particles, which appear to be defective interfering particles, may constitute a factor in the persistence of noncytocidal hepatitis B virus infection in man, as represented by the asymptomatic chronic HBsAg carrier.

6730 DISTRIBUTION OF D AND Y SUBTYPES IN AUSTRALIA ANTIGEN (AuAg)-POSITIVE LIVER DISEASES.

(Ger.) Kindler, U.; Schoppe, W. D.; Arnold, H. G. (I. Med. Klinik A der Universitat, 4000 Dusseldorf, Moorenstrasse 5, W. Germany). *Med. Welt* 26(37):1635-1637; 1975.

The role of the D and Y subtypes in Australia antigen (AuAg)-positive liver diseases was examined in 94 patients. The D subtype was found in 38 cases of acute hepatitis, 5 cases of chronic persisting hepatitis, 2 cases of chronic active hepatitis, and in 3 cases of cirrhosis. The Y subtype was found in 37 acute hepatitis cases, 5 chronic persisting hepatitis cases, and 3 chronic active hepatitis cases. The sex distribution within the subtypes was normal. In patients under 30 yr, the Y subtype predominated, while in those over 30, the D subtype was predominant. Only the D subtype was found in five cases with transfusion anamnesis; the Y subtype was found in seven cases of drug dependency. In parenteral "injection anamnesis," there were 16 cases of D and 12 cases of Y. Among paramedical personnel, D was positive in 8 and Y was positive in 10. Similarly, in patients with either contact or parenteral infection, D was found in four and Y in three. Prodromal liver diseases were not preferentially biased toward subtype, but certain correlations with biochemical variables were found. In subtype D, the maximum GOT level exceeded 1,000 mU/ml more frequently than did the level in Y. GPT and serum transaminase showed no subtype correlation. The subtype distribution in the ratio of diseases with complications to those without complications was 13:22 for D and 10:24 for Y. There was no preferential subtype bias in 13 of 23 cases of fulminating, cholestatic, persistent, or recurrent hepatitis in patients who had taken potentially hepatotoxic drugs (barbiturates, chloramphenical, or laxatives) before the onset of the disease. Although AuAg subtypes are important epidemiological indicators, they are not pathognomonic of acute liver diseases.

6731 e-ANTIGEN IN ACUTE AND CHRONIC HEPATITIS. (Ger.) Fay, O. H.; Tanno, H.; Roncoroni, M.; Findor, J.; Igartua, E. B.; Domecq, R. (Inst. Biochemical Studies, Mitre 1174, Rosario, Argentina). *Leber Magen Darm* 5(4):140-142; 1975.

The presence of early (e)-antigen was correlated with the clinical course of different forms of hepatitis. The test sample included 88 cases of hepatitis B antigen (HBs)-positive acute hepatitis with rapid healing (group 1); 75 patients with HBs-negative acute hepatitis with rapid healing (group 2); 15 cases of HBs-positive acute hepatitis that developed into the chronic form (group 3); 94 patients with HBs-positive chronic liver disease, including chronic active hepatitis, persistent hepatitis, and cirrhosis (group 4); and 50 cases of HBs-negative chronic liver disease, including 31 cirrhotics. In group 1, the e-antigen was found in nine patients; it was found in none of the group 2 patients. Eight patients in group 3 were e-antigen-positive with acute hepatitis, and remained positive during the chronic course of the disease. In group 4, 48 patients were e-antigen-positive, and in group 5, none were positive. Of the 197 HBs-positive patients, 65 (33%) were also e-antigen-positive, independent of disease type. Eight of 17 (47%) e-antigen-positive cases developed a chronic form, and 7/86 e-antigen-negative cases healed spontaneously, i.e., developed chronically. E-antigen is assumed to play a role in the etiology of chronic hepatitis.

6732 HUMORAL AND CELLULAR IMMUNE PHENOMENA IN ACUTE VIRAL HEPATITIS. (Ger.) Sodomann, C.-P. (Medizinische Universitatsklinik, D-3550 Marburg/Lahn, Mannkopffstrasse 1, W. Germany). *Leber Magen Darm* 5(4):123-131; 1975.

The significance of immune events in viral hepatitis A and B is reviewed. Initially, the relative and absolute counts for thymus lymphocytes are depressed, while the counts for "null" cells are elevated. Mild elevation in serum globulin levels occurs: immunoglobulin M (IgM) augmentation is fast, pronounced, and long-lasting, while IgG augmentation occurs later, is less pronounced, and is shorter lived. In some patients, low titers of autoantibodies to smooth muscle and mitochondria arise, as well as specific antibodies to the "early"-antigen and antibodies to the hepatitis A antigen (HBAg) in some hepatitis B cases. Immune complexes (i.e., HBAg, IgG, and probably IgM and IgA) and complement develop in some cases; levels of the fourth component of complement become depressed, and in cases complicated by allergic symptoms, there may be a decrease in C_3, C_4, and total complement. Activation of lymphocytes (virocytes) occurs in the peripheral blood. Enhanced spontaneous lymphocytic DNA synthesis develops as well as enhanced phytohemagglutinin stimulation of lymphocytes. During the acute and convalescent stages of hepatitis B, there may be a mild proliferation of lymphocytes to HBAg. In some hepatitis B patients, a migration inhibiting factor to the liver specific protein of lymphocytes is produced. In addition, the origin and diagnostic and prognostic importance of the immune phenomena are discussed.

LIVER AND BILIARY TRACT

Chronic Hepatitis

6762 CHRONIC PERSISTING HEPATITIS IN CHILDHOOD. (Ger.) Scholz, H. (Stadtisches Klinikum Berlin-Buch, 1115 Berlin-Buch, E. Germany). *Kinderaerztl. Prax.* 43(2):54-61; 1975.

Experiences in the management of pediatric chronic persisting hepatitis are reported. The clinical sample included 11 girls and 8 boys, 6-months-13 yr of age. Etiology in the majority was acute viral infection, at least four of which followed from contact. Only one case was frankly icteric. The physical status of the group at the onset of disease was generally satisfactory. Laparoscopy found periportal and interlobar infiltration and slight fibrosis in the periphery of the lobes or focal proliferation in 16 of the children during the first 6 months of observation. Eight cases received long-term therapy, including two with azathioprine alone, one with prednisolone alone, and two with azathioprine for 10 months, followed by corticoids. Azathioprine and prednisolone led to histologically active foci in two patients, which subsequently regressed in 1 yr; in another case with hepatomegaly and negative paraclinical data, gradually reduced doses of both drugs after 1 yr failed to suppress the onset of active hepatitis, for which prednisolone alone was subsequently given. Prednisolone is the drug of choice. In general, 3 mg/kg/day were administered for 4 weeks, after which the maintenance dose was reduced to 1 mg/kg/day, two or three times daily. Where histologically indicated, the dose can be reduced to 10 mg every other day. A 2-yr observation period is required.

6763 CHRONIC HEPATITIS FROM THE PATHOLOGIST'S POINT OF VIEW. (Ger.) Korb, G. (Pathologische Institut, Stadtische Krankenhaus, 8480 Weiden/Opf., Bismarckstrasse 30, Germany). *Therapiewoche* 25(27):3752-3760; 1975.

The nomenclature and nosology of chronic hepatitis, morphological criteria in the differential diagnosis of the active and persistent chronic types, and the need for collaboration between clinician and pathologist are briefly discussed. Chronic hepatitis does not include all non- or subacute liver inflammations, among which nonspecific reactive hepatitis, sclerosing pericholangitis, alcohol inflammation, and primary biliary cirrhosis are mentioned. Persistent chronic hepatitis is an inflammation without essential impairment of liver function and with no progressive tendency. It features infiltration of portal fields by predominantly lymphoid cells, and lamellar integrity remains without significant lobular change. In chronic persisting hepatitis, the lamellae are interrupted by "piece-meal" necroses and lobular irregularities; disturbances in portal field structure and evidence of incipient cirrhosis are best determined by laparoscopy.

6764 CHRONIC ACTIVE HEPATITIS. A CLINICAL, BIOCHEMICAL AND SEROLOGICAL INVESTIGATION. (Dan.) Dietrichson, O. (2. medicinsk afdeling, Kommunehospitalet, DK-1399 Copenhagen K, Denmark). *Ugeskr. Laeger* 137(32):1820-1825; 1975.

The various clinical, biochemical, immunological, and serological variables of chronic active hepatitis without cirrhosis are described. Eighty-five patients with confirmed chronic active hepatitis were examined. Forty-seven cases began as acute viral hepatitis, 19 had serum hepatitis, and 6 had infectious hepatitis. Symptoms included fatigue (77), malaise (73), dark urine and light stools (67), jaundice (66), weight loss (65), abdominal pain (61), itching (27), arthralgia (24), constipation (18), and fever (18). Antinuclear antibodies were present in 46 cases, mitochondrial antibodies in 1 case, smooth muscle antibodies in 30 cases, positive Waaler-Rose results in 8 cases, positive latex test in 32 cases, postive antistreptolysin results in 11 cases, and Australia antigen in 19 cases. The patients could be divided into two groups. One group was marked by the occurrence of the Australia (hepatitis B) antigen, while the other group was marked by circulating auto-antibodies. The first group probably originated from an initial viral infection, and the second group from an immune reaction to the laxative, oxyphenisatin. The second group had higher test levels for aspartate transaminase, serum bilirubin, alkaline phosphatase, immunoglobulin G (IgG), IgA, IgM, the latex test, and the LE-cell test; their mean age was also double that for the first group. It is probable that there are other subdivisions of chronic active hepatitis without cirrhosis.

6765 CHRONIC PERSISTING HEPATITIS. A CLINICAL, SEROLOGICAL AND PROGNOSTIC STUDY. (Dan.) Dietrichson, O. (2. medicinsk afdeling, Kommunehospitalet, DK-1399 Copenhagen K, Denmark). *Ugeskr. Laeger* 137(32):1815-1819; 1975.

Chronic persisting hepatitis is described with a view to contributing to a method of diagnosis. Of the 26 confined cases seen in a 7-yr period, 22 began with acute hepatitis, of which 16 had been diagnosed as acute viral hepatitis after biopsy. Sixteen of the patients had serum hepatitis induced by practices common among addicts. Initial symptoms had been abdominal pain (21), malaise (21), fatigue (20), weight loss (18), jaundice (16), dark urine and light stools (16), itching (9), arthralgia (7), constipation (5), fever (5), and skin rash (1). Seven patients had positive Latex test results, six were positive for antistreptolysin, and 12 were positive for Australia antigen. Follow-up studies showed the development of cirrhosis in one patient and severe portal fibrosis in another. Three patients still had chronic persisting hepatitis 28 months later. Chronic persisting hepatitis may be a result of acute viral hepatitis. Chronic persisting hepatitis may be confused with chronic aggressive hepatitis in a stage of lowered activity, which may explain the seemingly low incidence of the disease. All patients with chronic persisting hepatitis should undergo follow-up biopsy.

6766 PROGNOSIS OF UNTREATED AND TREATED CHRONIC ACTIVE HEPATITIS. (Ger.) Knoblauch, M.; Ammann, R.; Clavadetscher, P.; Grob, P.; Schmid, M. (Leitender Arzt, Medizinische Klinik, Kantonsspital, CH-8091 Zurich, Switzerland). *Schweiz. Med. Wochenschr.* 106(9):315-316; 1976.

The outcome of long-term management of chronic active hepatitis, with or without cirrhosis, was analyzed in 121 cases. Patients with subacute necrotizing hepatitis and terminal cirrhosis were excluded. The average treatment interval was 5 yr, 4 months; 106 patients were followed more than 3 yr. Therapy consisted of initial steroids, subsequent combinations of steroids and azathioprine, and a maintenance regimen of 10-15 mg prednisone and 50-100 mg azathioprine. Six patients died of hepatoma, and 23 died of cirrhosis (24%). Mortality in an untreated group was 33%; in the long-term management group, mortality was 11%, and in a group under short-term control (where only the crisis was treated), mortality was 25%. After 3 yr, mortality was 20% in the untreated group, 12.5% in the short-term treatment group, and 5.5% in the long-term treatment group. After 5 yr, mortality was 25% in untreated patients, 17.5% in short-term treatment, and 5.5% in long-term treatment. Long-term mortality was significantly less than that in untreated patients at 1, 3, and 5 yr. Mortality was 50% in 20 patients with concurrent autoimmune diseases. Patients with chronic active hepatitis 2b and cirrhosis had a 57% mortality. At the end of the observation, 36 cases of inactive cirrhosis included 30 under treatment. Complete healing occurred in 13 noncirrhotic chronic active hepatitis patients, with equal distribution among the treatment groups. Transitions from 2a to 2b or 2b to 2a appeared with equal frequency in treatment and nontreatment groups.

6767 CORRELATION BETWEEN FUNCTIONAL DIAGNOSIS AND HISTOLOGY IN CHRONIC HEPATITIS IN CHILDHOOD. (Ger.) Burdelski, M.; Lucking, Th.; Natzschka, J. (Kinderklinik, Medizinische Hochschule, Karl-Wiechert-Allee 9, D-3000 Hannover 61, W. Germany). *Monatschr. Kinderheilkd.* 124(5): 380-381; 1976.

The relation between the degree of histological change and serum enzyme or protein levels, independent of the type of chronic hepatitis, and between the serum levels and hepatitis type was examined in 15 patients aged 7 months to 14 yr. Chronic persistent hepatitis (CRH) was confirmed in 10 patients, and chronic progressive hepatitis (CGH) was confirmed in 9. Three patients with CGH were also cirrhotic. Aspartate aminotransferase (SAT), alanine aminotransferase (LAT), and glutamic dehydrogenase (GDH) were slightly to moderately elevated in all patients, with corresponding parenchymal changes; no difference between CRH and CGH could be established. Cholinesterase was unchanged. Gamma-glutamyl transpeptidase (GGT) was insignificantly higher in CGH, especially with cirrhosis, than in CRH, but was somewhat lower than in six children with chronic hepatosis (CHT). The SAT/LAT quotient was approximately the same for CRH, GGH, and CHT. The SAT + LAT/GDH value was insignificantly larger in CGH than in CRH or CHT. Although unity was exceeded in individual cases of CGH for the GGT/SAT ratio, the group differences were insignificant. The gamma-globulin fraction was significantly higher in CGH than in CRH or CHT, whose values were normal. Total immunoglobulin and immunoglobulin G were also significantly higher in CGH than in CRH. A typical enzyme pattern, unique to CGH, CRH, or CHT, could not be established. Elevations in enzyme activity were correlated with the degree of parenchymatal inhibition, which, with histological complementation, could be diagnostically reliable in individual patients.

6768 LONG-TERM IMMUNOSUPPRESSIVE THERAPY OF CHRONIC ACTIVE HEPATITIS. (Ger.) Schimmelpfennig, W.; Schneider, G.; Wagner, K.; Wack, R.; Lunzenauer, K. (II Med. Klinik [Charite], 104 Berlin, Schumannstrasse 20/21, Berlin, E. Germany). *Z. Gesamte. Inn. Med.* 30(23):271-273; 1975.

Experiences with immunosuppressive management of 47 cases of chronic active hepatitis are reported; 13 cases were Australia antigen (AuAg)-positive. Therapy consisted of 100 mg azathioprine and 10 mg prednisolone daily; 30 patients had previously received prednisolone alone without effect. The mean therapeutic interval was 33.8 months. Hepatomegaly was reduced in about one-third of the cases. Significant ($p<0.01$) serological normalization (thymol, $ZnSO_4$, GOT, GPT) was achieved in 4/9; electropherography and alkaline phosphatase were unchanged. Histologic amelioration was confirmed in 22/47 during punch biopsy control in an average of 3 yr; 4 patients showed exacerbation, and 10 were unaffected. A transition from the chronic active to the chronic persisting form occurred in 11/47, with augmented stromal proliferation in 6. Within 4-31 months, patients succumbed from cirrhosis and portal hypertension. Cytopenia and gastrointestinal sequelae did not appear. Rebound was present in three cases. In the AuAg-positive group, mortality was 3/13, with histological amelioration 6, exacerbation in 2, and no change in 2. A preference for combination therapy of azathioprine and reduced prednisolone (5-10 mg/day) is cited.

6769 PROBLEMS IN THE TREATMENT OF CHRONIC AGGRESSIVE HEPATITIS WITH CORTICOSTEROIDS, IMMUNOSUPPRESSIVES, AND PENICILLAMINE. (Ger.) Muting, D.; Fischer, R. (Ltd. Arzt. der Heinz-Kalk-Klinik fur Innere Medizin-Gastroenterologie, 8730 Bad Kissingen-Hausen, Am Gradierbau). *Therapiewoche* 25(27):3737, 3740, 3745-3748, 3751; 1975.

Therapeutic modalities for chronic aggressive (AH) hepatitis were analyzed. The bases of management included complete bed rest and alcohol abstinence; there was no treatment of choice. Positive results have been reported for combined prednisolone (PDN) and azathioprine (AZT) especially in early CAH; PDN should not exceed 12.5 mg, and AZT, 50-100 mg per day. Side effects include thrombopenia, leukopenia, megaloblastic anemia, portal hypertension, and hepatotoxicity. One 46-yr-old man was effectively managed initally by PDN, and later by AZT, with PDN reduced to 2.5 mg before the onset of inflammatory change and transition to incipient cirrhosis. Histological improvement followed renewal of combined PDN-AZT therapy, but succinic dihydrogenase increased and an inactive tuberculosis lesion became active. Although PDN was found to be significantly superior to AZT in monotherapeutic double blind studies, its side effects are extensive and severe. Long-term therapy with D-penicillamine (DPA), which is not antibiotic, has been effective against Wilson's disease; the side effects are not inconsiderable, so its use should be limited to inpatient intervals. Nine positive results, with one allergic exanthematous complication and one negative result, were obtained with DPA in 2.5-14 months. Only one improvement after 1 yr followed DPA management of four actively cirrhotic patients without portal hypertension. A statistical survey of 352 CAH patients under a variety of treatments found that only 12% were exacerbated, 50% arrested, and 20% improved.

6770 RESULTS OF A LONG-TERM STUDY ON THE THERAPEUTIC EFFECTIVENESS OF XANTHINOL NICOTINATE IN CHRONIC LIVER DISEASE. (Ger.) Dohrmann, R. E.; Kessel, M. E. (Ev. Waldkrankenhaus Spandau, 1 Berlin 20, Stadtrandstrasse 555, W. Germany). *Z. Allgemeinmed.* 51(26):1167-1172; 1976.

The effectiveness of xanthinol nicotinate (XN) in the management of various liver diseases was evaluated in 100 patients. There were 26 cases of fatty liver, 15 of fibrosis, 15 of cirrhosis, 9 of both fibrosis and cirrhosis, 8 of fatty liver and fibrosis, 6 of chronic hepatitis, 3 of chronic active hepatitis, 6 of persistent chronic hepatitis, and 4 of chronic hepatitis and fibrosis. Acute viral hepatitis and pathology secondary to gallbladder dysfunction were excluded. Treatment of choice was thiamine hydrochloride, whose infusion ampules contain 1,000 mg of XN. The maximum daily infusions (3-4 hr) contained 3,000 mg of XN. After clinical or paraclinical improvement, usually following a 4-week treatment, medication was reduced to a maximum daily dose not exceeding 900 mg XN. Blood chemistry was checked every 10-14 days and on suspension of XN; liver biopsies were also performed. Bed rest was mandatory. Results were compared with those from a control group of 12 patients with liver diseases, but not receiving thiamine hydrochloride. Serum bilirubin, SGOT, SGPT, and BSP retention levels were all reduced by an average of 43-67% ($p<0.001$) from initial levels after both forms of Metabolan. Albumins and gamma-globulins were only slightly increased and decreased, resp. After infusion therapy (63 cases) alone, the values fell an average of 47-66% ($p\leq0.001$; BST $p\leq0.02$), with the serum proteins showing the same pattern. In the control group, the reduction was 67% for serum bilirubin, 81% for SGOT, 85% for SGPT (all at $p<0.001$), and 31% for BSP ($p=0.40$). The albumins rose slightly, and the globulins remained unchanged. A majority of patients experienced relatively rapid general improvement. Flush reactions and skin allergies occurred in 2%, and two cases of chronic active hepatitis became persistent chronic hepatitis during XN therapy. The case histories are presented. Despite a similar normalization of serum levels in controls, XN is said to affect both the liver parenchyma and its hemodynamics favorably.

6771 PROBLEMS OF IMMUNOSUPPRESSIVE AND MESENCHYMA-SUPPRESSIVE THERAPY OF INFLAMMATORY DISEASES OF THE LIVER. (Ger.) Zipprich, B.; Busse, H. J.; Nilius, R.; Otto, L. (I. Medizinische Universitatsklinik, 402 Halle [Saale], Leninallee 22, E. Germany). *Z. Aerztl. Fortbild. (Jena)* 70(2):62-66; 1976.

Immunological phenomena in liver disease are reviewed, and experiences with D-penicillamine (DPA) therapy for active chronic hepatitis are discussed. DPA was given to 18 patients in increasing doses of from 0.9 to 1.8 g/day, with a maintenance dose of 0.9 g/day, combined with 60 mg/day of vitamin B_6. Suspension of medication was required in four cases due to intractable side effects. Normalization or amelioration was achieved in most cases, according to thymol, SGOT, SGPT, and leucine aminopeptidase values. One case with incipient cirrhosis and another with incipient primary biliary cirrhosis were exacerbated. Side effects included nephrotic syndrome, gastroenteritis, multiform exudate erythema, and taste disturbances.

6772 CELLULAR IMMUNE REACTIONS IN CHRONIC INFLAMMATORY LIVER DISEASE: TECHNIQUES. THE EVALUATION AND DIAGNOSTIC SIGNIFICANCE OF FINDINGS. (Ger.) Meyer zum Buschenfelde, K. H. (II Med. Univ.-Klinik, Johannes-Gutenberg-Universitat, 65 Mainz, Langenbeckstr. 1, W. Germany). *Z. Gastroenterol.* 13(Suppl.):252-256; 1975.

Functional tests of the thymus-dependent immune system and results of the one-phase and conventional two-phase methods of migration inhibition for the diagnosis of chronic active hepatitis were reviewed. The crucial antigen must be a liver-specific macrolipoprotein from hepatocyte plasma membranes. Untreated patients with chronic active hepatitis (HBsAg-negative) exhibit migration inhibition relative to hepatocyte plasma membranes in 75%-80% of the cases. The cytotoxicity for hepatocytes elicited with peripheral lymphocytes from chronic active hepatitis can be inhibited with purified hepatocyte plasma membrane. In HBsAg-positive hepatitis, the frequency of positive findings is significantly lower. Transient cellular immune reactions relative to hepatocyte plasma membrane are also demonstrable in acute viral hepatitis and alcohol-induced hepatitis, suggesting that cell-mediated reactions are inducible by different factors. The one- and two-phase methods also demonstrate immune reactions to HBsAg in patients with acute HBsAg-positive hepatitis. It is inferred that a cell reaction to HBsAg can be routinely shown in acute virus-B hepatitis patients who are HBsAg-negative during the disease. Cell reactions to HBsAg are rarely demonstrable in chronic HBsAg carriers (healthy persons or patients with chronic liver inflammation).

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

6776 COMPARATIVE LIGHT AND ELECTRON MICROSCOPIC STUDY OF LIVER CELL INCLUSIONS IN CHRONIC ALCOHOLIC LIVER DAMAGE. (Ger.) Stotzner, H.; Kemmer, Ch. (Pathologisches Institut, Medizinische Akademie "Carl Gustav Carus," 8019 Dresden, Fetscherstrasse 74, E. Germany). *Zentralbl. Allg. Pathol.* 119(5):378-386; 1975.

The ultrastructural identification of hepatocyte inclusions in 15 patients with ethanol hepatosis or hepatitis was compared with light microscopy correlates. Autophagic vacuoles stained eosinophilic and are strongly PAS-positive before and after diastase. Giant mitochondria (megamitochondria) were eosinophilic and PAS-negative, with bizarre shapes, cristae accumulations, and paracrystalline deposits. Alcoholic hyaline was nonuniformly shaped, with irregular fibrils, and was typically PAS-negative and weakly basophilic; ribosomes could be embedded. Ribosomal clusters were basophilic, occurring as free polysomes or bound to proliferating membranes of endoplasmic reticulum. The bile deposits were polymorphic, PAS-positive, and of greenish hue when fresh, corresponding electron microscopically to eosinophilic cytoplasmic inclusions, mainly from altered endoplasmic reticular membranes. Bile inclusions were attributed to lysosomal degradation and homogenization. Autophagic vacuolization has not been previously described light microscopically. None of the inclusions described were pathognomic.

LIVER AND BILIARY TRACT

Cirrhosis

6781 CHANGES IN BONE MARROW MORPHOLOGY IN CHRONIC LIVER DISEASE. (Ger.) Muhiar, A. F.; Konrad, H. (Bereich Medizin, Universitat Rostock, 25 Rostock 1, Ernst-Heydemann-Strasse, E. Germany). *Wiss. Z. Univ. Rostock* 23(4/5):353-358; 1974.

The question of qualitative or quantitative changes in bone marrow secondary to liver pathology was explored. The clinical sample included 44 patients with cirrhosis, 26 with chronic hepatitis, 10 with fatty liver, 24 with liver stasis, 7 with benign occlusion icterus, and 16 with liver metastases. Sternal puncture cellularity found the following normoplastic, hyperplastic, and hypoplastic distribution, resp.: 21, 17, and 6 for cirrhotic patients; 15, 8, and 3 for those with chronic hepatitis; 7, 2, and 1 for fatty liver patients; 19, 3, and 2 for liver stasis; 6, 1, and 0 for occulsion icterus; and 11, 3, and 2 for liver metastases. Signs of portal hypertension and latent hemolysis occurred in several hyperplastic cases; hypoplastic marrow was characteristic of chronic disease with few complications. Myelography found erythropoiesis more pronounced in cirrhosis, with a conspicuous left shift in chronic hepatitis, liver stasis, and metastases. Chronic disease was associated with elevated myeloblasts and promyelocytes. Metamyelocytes and immature forms were most pronounced in cirrhosis and metastases, but a left shift was found in all groups. Qualitative myelopoietic malfunction (toxic granulation and neutrophil vacuolization) was only found sporadically in cirrhosis and liver metastases. The myelopoietic:erythropoietic quotient was depressed in all groups. Lymphocyte counts were low in all patients, especially those with chronic hepatitis and fatty liver; monocytes were also diminished. Reticular cells were increased in cirrhosis and liver metastases. Plasma cells were more frequent in all groups, especially cirrhosis and liver metastases; megakaryocytes were lower in each patient group. A comparison was made with sternal puncture pictures from 10 healthy persons. None of the cell variables studied are pathognomic of specific liver embarrassment. Marrow stimulation is found in all chronic disease. Differences occur only quantitatively, gradually by degrees.

6782 PRIMARY BILIARY CIRRHOSIS. CLINICAL, BIOLOGICAL AND HISTOLOGICAL STUDY. (Fre.) Demol, P.; De Groote, J.; Desmet, V. (Academisch Ziekenhuis St-Rafael, Capucijnenvoer 35, B-3000 Leuven, Belgium). *Acta Gastroenterol. Belg.* 38(9/10):314-328; 1975.

Eleven cases of primary biliary cirrhosis (8 women and 3 men, aged 49-76 yr) are reported with a clinical, histological, and biologi-

LIBRARY U. OF I.

cal review. All patients presented with symptoms of pruritus, moderate icterus, and hepatomegaly; three patients had xanthelasmatosis, and five had splenomegaly. Associated autoimmune syndromes were absent and complications were rare (1 osteomalacia, 2 osteoporoses, and 1 esophageal varice). Two patients suffered from hepatocellular insufficiency; there were no hepatic comas, which are the most frequent cause of death in this syndrome. Treatment (cholestyramine or prednisone with azathioprine) did not appear to influence evolution of the disease. The patients were followed for a period of 1.5 to 10 yr and the course of illness was slightly worse in the treated patients.

6783 DIFFUSION DISTURBANCES IN PATIENTS WITH LIVER CIRRHOSIS. (Ger.) Schomerus, H.; Hilpert, P. (Medizinische Univ.-Klinik, Abt. I und II, D-7400 Tubingen, W. Germany). *Z. Gastroenterol.* 14(3):378-387; 1976.

The changes in the diffusion potential (DP) of pulmonary alveolar membranes (AM) and capillary blood volume (CV) in contact with alveoli were investigated in 17 patients with confirmed cirrhosis, and compared with 11 controls without liver or lung pathology. The sitting patients inhaled a mixture of 21% O_2, 12% He, 0.3% CO and nitrogen, submaximally, and exhaled after a 9-10-sec apnea. After discarding the first liter of air, the alveolar air was assayed for O_2, He, and CO, and the values of the alveolar variables were established. There was no radiological, clinical, or functional evidence of primary lung disease in the patients. The average total lung DP for CO was significantly lower ($p<0.01$) in patients than in controls, which is attributable to an elevated AM resistance. The average DP for AM was also lower in patients than in controls, but the capillary volume in patients was somewhat higher. The CV variation was significantly higher ($p<0.01$) in patients than in controls. The greatest increases in CV were associated with the lowest DP or AM, such that the total resistance was in the normal range. A significant ($p<0.001$) correlation between CV and DP of AM was established in patients. The ventilatory or perfusion dysfunctions reported for cirrhotic patients could not be confirmed.

6784 SERUM-GASTRIN IN CIRRHOSIS. (Eng.) Lauritsen, K. B.; Rehfeld, J. F.; Christiansen, L. A.; Juhl, E.; Stadil, F. (Undervisningsparillon 1 Bispebjerg Hosp., 2300 Copenhagen NV, Denmark). *Scand. J. Gastroenterol.* 11(37):33-34; 1976.

To investigate the relation between increased serum gastrin levels and cirrhosis, the basal serum gastrin concentrations were measured in 50 cirrhotic patients grouped according to alcohol consumption and cirrhotic activity. Alcoholism was defined as a daily intake of five or more drinks during a period of 5 yr or longer, and 27 patients fit into this category. Activity of the liver disease was graded as follows: inactivity, normal gammaglobulin and SGPT concentrations; slight activity, two- to threefold increases in one or both parameters; and moderate and severe activity, a more than threefold increase in one or both parameters. In 120 normal subjects, the mean serum gastrin concentration was 24 pM, while in the cirrhotic patients it was 45 pM ($p<0.05$). In the patients with alcoholic cirrhosis, the mean gastrin concentration was only slightly enhanced (29 pM), while that in the 23 patients with nonalcoholic cirrhosis was highly increased (64 pM, $p<0.01$). The mean concentrations in the patients with slightly active disease were increased both in the alcoholic patients (22 pM) and the patients with nonalcoholic cirrhosis (34 pM) in comparison with those in inactive disease (32 and 96 pM in alcoholic and nonalcoholic cirrhosis, resp.) These findings support the suggestion that the liver plays a significant role in the metabolism of circulating gastrin.

6785 EMERGENCY AND ELECTIVE SURGICAL TREATMENT OF PORTAL HYPERTENSION. A REVIEW OF 23 YEARS' EXPERIENCE. (Eng.) Kirby, R.; Burke, F. D.; Jones, J. D. T. (General Hosp., Hartlepool, England). *Ann. R. Coll. Surg. Engl.* 57(3):148-158; 1975.

A retrospective review of surgical treatment for portal hypertension in 160 patients during a 23-yr period is reported, and the immediate and subsequent management of patients with bleeding esophageal varices is discussed. Fifty-four patients with recurrent varix hemorrhage, uncontrolled by conservative methods, were treated by esophageal transection, with a mortality of 22.2% (26.6% for the 46 cirrhotics). Thirty-two percent of the cirrhotics were alive after 2 yr, but only 12% of the survivors were considered suitable for a subsequent shunt procedure. Therapeutic portacaval anastomosis was performed on 65 patients, with a 51.2% 5-yr survival (43.5% for cirrhotic patients). Further hemorrhage due to shunt thrombosis occurred in 5.3% of the cases. The frequent occurrence of portal-systemic encephalopathy, increasing with duration of time following a shunt, is emphasized. The high morbidity and mortality in the poor-risk cirrhotic indicates that this type of patient is unsuitable for a portal-systemic shunt and is better treated by medical means.

6786 CLOTTING DISORDERS IN PORTAL HYPERTENSION. (Ger.) Heene, D. L. (Zentrum fur Innere Medizin, Justus-Liebig-Universitat Giessen, D-63 Giessen, Klinikstrasse 32 b, W. Germany). *Z. Gastroenterol.* 13(3):147-157; 1975.

A review of the multiple clotting dysfunctions constituting the clinical picture of cirrhosis with portal hypertension is presented. The hemostatic defect in cirrhosis with portal hypertension is an expression of a multiple pathological event whose clarification by the most subtle assays is not possible. In addition to the reduction in vitamin K-dependent factors, there are also metabolic disturbances. Dysfunction in splanchnic microcirculation induced by portal hypertension is probably the triggering factor. Exacerbation of the intravascularly increased turnover disturbances, such as consumption, coagulopathy, or secondary fibrinolysis, results from an impaired equilibrium between inhibitors, activators, and reticuloendothelial clearance capacity.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

6793 SYSTEMIC ABSORPTION OF CONTRAST AGENT DURING ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY. (Eng.) Kaufman, B.; Gambescia, R.; Maldonado, A.; Raskin, J. B. (Jackson Memorial Hosp., 1611 NW 12th Ave., Miami, FL 33136). *Gastrointest. Endosc.* 22(3):175-176; 1976.

A case that clearly illustrates that absorption of a contrast agent, Meglumine diatrizoate, can occur is presented. Intravenous cholangiography was performed in a 42-yr-old woman for the evaluation of recurrent midepigastric pain. She had undergone cholecystectomy 4 yr previously. The results of cholangiography suggested a distal stricture or small stone in the common bile duct, and endoscopic retrograde cholangiopancreatography was performed. Meglumine diatrizoate was injected by hand pressure, and opacification of the main pancreatic duct was obtained. With slow withdrawal and continuous gentle injection, opacification of the common bile duct was accomplished. Both ductal systems were normal. During the injection, the patient experienced mild midepigastric discomfort while an intense pancreatic acinarization was noted. Concomitantly, the bladder was visualized with a bilateral excretory urogram. Afterward, the patient experienced moderate epigastric pain, which resolved after 24 hr. The serum amylase level was increased immediately after the procedure (732 Somogyi U), as was serum lipase (12 IU). This case demonstrates that absorption of a contrast agent during endoscopic retrograde cholangiopancreatography can occur; pancreatic acinarization was unusually prominent in this case, and probably played a significant role.

6794 PERCUTANEOUS TRANSHEPATIC CHOLANGIAL DRAINAGE: DIRECT APPROACH UNDER FLUOROSCOPIC CONTROL. (Eng.) Takada, T.; Hanyu, F.; Kobayashi, S.; Uchida, Y. (Inst. Gastroenterology, Tokyo Women's Medical Coll., 10 Kawadd-cho, Shinjuku-ku, Tokyo, Japan). *J. Surg. Oncol.* 8(1):83-97; 1976.

A method for direct percutaneous transhepatic cholangial drainage under fluoroscopic control is described. After percutaneous transhepatic cholangiography, the three-dimensional view of the intrahepatic bile ducts is projected onto a two-dimensional plane under fluoroscopy. When the puncture needle, which is covered with a Teflon tube, is introduced perpendicular to this plane in the ventrodorsal direction, it is possible to accurately puncture the selected bile duct, which is then intubated. The procedure was performed on 99 highly jaundiced patients, including 14 with carcinoma of the head of the pancreas, 4 with papilla carcinoma, 24 with bile duct and gallbladder carcinoma, 41 with metastatic carcinoma to the bile duct, and 16 with gallstone disease. In 38 of these patients, including those with gallstone disease, the technique was performed preoperatively as a preliminary decompression of the bile ducts; 28 of these patients successfully underwent radical surgery. A total of 16 patients with gallstone disease received this procedure because of severe cholangitis; five of these cases were complicated with multiple hepatic abscesses that were correctly diagnosed and successfully treated by drainage technique. In another 61 patients with inoperable advanced cancer, the technique was used to relieve jaundice; 30 of these patients showed less jaundice for more than 3 months, and 19 showed less jaundice for more than 6 months. The lives of four of these patients were prolonged for more than 1 yr when the drainage technique was followed by radiation therapy and anticancer drugs. Severe complications, such as bile leakage or intraperitoneal hemorrhage, were not observed in any of the patients treated with the above procedure. Hemobilia was noted in some cases, but did not require blood transfusions. Fever (37-38 C) occurred in some patients as a result of an elevation of the inner pressure of the bile ducts, caused by reobstruction of bile flow through the tube.

6795 CHOLECYSTECTOMY. STATISTICS, INDICATIONS, COMPLICATIONS. (Ger.) Schreiber, H. W.; Schumpelick, V.; Bartelheimer, H. (Chir. Univ.-Klinik, 2 Hamburg 20, Martinistrasse 52, W. Germany). *Med. Welt* 27(3):95-100; 1976.

Experience with cholecystectomy and its sequelae are reviewed. The clinical sample included 1,842 cholecystectomies, 329 bile duct revisions, 272 transduodenal papillectomies, 27 choledochoduodenostomies, and 23 other operations. The average patient age was 54 yr (514 cases) for men and 51 yr (1,979 cases) for women. The mortality from cholecystectomy was 23 patients (average age, 66 yr). In contrast to papillectomy and ductal revision, the cause of mortality in these patients was associated with advanced age and involved cardiovascular, pulmonary, or renal complications; mortality was only 0.4% in the group under 40 yr. The experience highlights the importance of early, low risk cholecystectomy.

6796 SUSCEPTIBILITY OF THE LIVER AND BILIARY TRACT TO ANAEROBIC INFECTION IN EXTRAHEPATIC BILIARY TRACT OBSTRUCTION. III. POSSIBLE SYNERGISTIC EFFECT BETWEEN ANAEROBIC AND AEROBIC BACTERIA. AN EXPERIMENTAL STUDY IN RABBITS. (Eng.) Nielsen, M. L.; Justesen, T.; Asnaes, S. (31 Sofievej, DK-2900 Hellerup, Denmark). *Scand. J. Gastroenterol.* 11(3):263-272; 1976.

The pathogenicity of single anaerobic, single aerobic, and mixed anaerobic and aerobic bacterial inocula was studied in three groups of 12 rabbits with experimentally induced biliary tract obstruction. *Bacillus fragilis, ss. fragilis,* and *Escherichia coli* serotype O1:K1:H7 were used. The investigation was made 7 days after bacterial inoculation, and included bacteriological studies of the liver and bile, as well as studies of liver function and morphology of the liver and biliary tract. The inoculation of 10^5-10^6 *E. coli* did not cause biliary tract infection, liver abscesses, or death. Inoculation of 10^9 *B. fragilis* caused biliary tract infection in 83% and liver abscesses in 17% of the animals inoculated, without any mortality. Combined inoculation with *B. fragilis* and *E. coli* in reduced doses significantly increased mortality (42%) and the frequency of liver abscesses in surviving animals (86%). All abscesses, however, yielded a pure culture of *B. fragilis* only. Eighty-four percent of the animals inoculated with *B. fragilis* alone or with *B. fragilis* in combination with *E. coli* developed biliary tract infection with *B. fragilis*, the bile yielding 10^7-10^9 *B. fragilis* per milliliter, gallbladder bile yielding significantly higher bacterial counts than common duct bile. *E. coli* was never recovered from bile in surviving animals, but from both bile and blood in animals not surviving the experimental period.

6797 PSEUDOLYMPHOMA OF THE GALLBLADDER. (Eng.) Hussain, S. A.; English, W. E.; Lytle, L. H.; Thomas, D. W., Jr. (Lock Haven Hosp., 112 W. Main St., Lock Haven, PA 17745). *Am. J. Gastroenterol.* 65(2):152-155; 1976.

The case of a 78-yr-old woman with pseudolymphoma of the gallbladder is presented. The patient had a 2-yr history of postprandial epigastric distress, "bloating," and retrosternal burining, which were relieved by carbonated drinks and alkalis. The gallbladder was found to be enlarged and nonfunctioning; it contained palpable stones, and a cholecystectomy was performed. The common bile duct functioned normally. The gallbladder contained a polypoid, finely nodular lesion that projected into the lumen of the proximal portion of the body. The lesion was covered by a thin layer of intact mucosa and was composed primarily of lymphocytic elements that tended to separate the smooth muscle fibers. The lymphocytes appeared mature, but varied slightly in size. The histiocytes contained active nuclei, but none had the appearance of Reed-Sternberg cells. Scattered throughout the lymphocytes were small vascular twigs. The pericholecystic lymph node showed hyperplasia, but no evidence of malignancy. The patient made an uneventful recovery. This case fullfilled all the criteria for the diagnosis of pseudolymphoma, except that giant cells were not observed. This is apparently the first reported case of pseudolymphoma of the gallbladder.

6798 CHOLECYSTOSTOMY HAZARD IN ACUTE CHOLANGITIS. (Eng.) Saik, R. P.; Greenburg, A. G.; Peskin, G. W. (Veterans Admin. Hosp., 3350 La Jolla Village Drive, San Diego, CA 92161). *JAMA* 235(22):2412-2413; 1976.

The cases of four patients with acute cholangitis, all of whom died following cholecystostomy or cholecystoduodenostomy, are presented. The first patient, a 50-yr-old man, had had a portacaval shunt for cirrhosis and variceal hemorrhage. The second, an 87-yr-old man, had had gastrectomy for peptic ulcer disease and had been treated for coronary artery disease. The third, an 83-yr-old man, had chronic pancreatitis. The fourth patient, a 69-yr-old man, had alcoholic cirrhosis and pulmonary tuberculosis and had had a gastrectomy. All patients were diagnosed as having acute cholecystitis, and cholecystostomy or cholecystoduodenostomy was performed instead of cholecystectomy. After the procedure, bile cultures were positive for bacteria; *Klebsiella* was found in three patients, *Escherichia coli* in three, *Staphylococcus aureus* in one, *Proteus* in two, and *Pseudomonas* in one. Despite extensive antibiotic treatment, all patients died in septic shock. Although cholecystostomy remains an adjunct for the treatment of severe acute cholecystitis, it is an inadequate method of drainage of the common duct, unless cystic duct patency can be verified. Immediate reoperation, rather than antibiotic manipulation, to establish common duct drainage in patients who do not respond to cholecystostomy within 24 hr is advised.

6799 VALUE OF EARLY OPERATION FOR CHOLELITHIASIS.

(Ger.) van der Linden, W. (Chirurgische Klinik, Centrallasarettet, S-83101 Ostersund, Sweden). *Internist (Berlin)* 16(12):571-574; 1975.

The risks associated with gallstones, the indications for early surgery in uncomplicated cases, the question of early or delayed intervention in acute cholecystitis, and the decision for cholecystostomy or cholecystectomy are reviewed. Surgery for cholelithiasis is considered mandatory, and the indications for it are no less compelling in patients with small stones than in those with single large ones. The question of early intervention in uncomplicated cases remains open, since some affected patients remain without complications for a lifetime; similarly, the question of geriatric intervention remains controversial. The inferential limit is that the surgery is simpler, and the risks smaller, for surgery in the early stages. The problem of operating during acute cholecystitis or waiting until the acute phase has passed has been explored in only one methodologically sound study; it concluded that early surgery was preferable to conservative management. Cholecystostomy, although technically easier than cholecystectomy, has a higher mortality and can require subsequent cholecystectomy; few patients remain symptom-free after cholecystostomy. The author believes that cholecystostomy should be considered only in emergencies and should otherwise be avoided.

6800 TOLERABLE TRANSAMINASE LEVELS IN CHENODEOXYCHOLIC ACID THERAPY.

(Ger.) Krille, G. (Hamburger Strasse 164, 2000 Hamburg 76, W. Germany). *Med. Welt* 27(11):546-547; 1976.

The problem of tolerable elevations in transaminases and exacerbated cholestasis, which are sequelae of chenodeoxycholic acid (CDA) litholysis, is explored and a case history is presented. An inoperable 66-yr-old man with stones, gallbladder hydrops, gastric polyps, hepatomegaly, and cholangic tides with cholestatic hepatitis received an initial dose of 1,500 mg/day CDA, with subsequent administration of 750 mg/day (250 mg mornings, 500 mg evenings). Both doses elicited diarrhea, but enzyme levels remained normal. Three months after the onset of CDA, the patient experienced epigastric pain and increasing gallbladder hydrops. Ten days later, after uninterrupted CDA, five stones were passed. All clinical and laboratory signs were subsequently normalized. After 3 months, the transaminase, γ-glutamyl peptidase, and bilirubin levels increased, and epigastric discomfort recurred. All were reduced with the passing of a sixth stone. Elevated transaminase is not a reason to interrupt CDA litholysis; CDA and CDA-induced lithocholic acid are not hepatotoxic.

6801 ISOENZYMES OF ALANINARYLAMIDASE AND GAMMA-GLUTAMYL-TRANSPEPTIDASE IN INTRAHEPATIC AND EXTRAHEPATIC CHOLESTASIS.

(Ger.) Bornschein, W. (Klinikum rechts der Isar, Technische Universitat Munchen, 8 Munich 80, Ismaninger Strasse 22, W. Germany). *Med. Klin.* 70(21):950-953; 1975.

The role of alanine arylamidase (AA) and gamma-glutamyl transpeptidase (GGT) isoenzyme quotients in the differential diagnosis of extra- or intrahepatic cholestasis was studied in 43 patients by gel electrophoresis. The sera of 24 patients with extrahepatic cholestasis (EHC) was compared with that from 19 patients with intrahepatic cholestasis (IHC). Two GGT bands were seen, one in the albumin alpha-1 region (ISO-1) which forms a weak second anodic band, and one in the alpha-2 region (ISO-2) in healthy subjects. Augmentation of the slowly migrating fraction (beta-globulin region) occurred in both cholestases. A third band was formed in cases of icterus and malignancy with prominent cholestases. The average total serum AA level was higher in EHC than in IHC. ISO-2 of AA is higher in EHC than in IHC, and it increases about equally in both IHC and EHC. The average total serum GGT is significantly higher in EHC than IHC. ISO-2 of GGT is higher in EHC than IHC. In EHC, 19 of 24 cases were of tumors of the bile ducts and head of the pancreas. The group with tumors and cholestasis (independent of localization) was significantly differentiable from the group with benign cholestases (also independent of localization). The role of isoenzyme values in the differential diagnosis of EHC and IHC probably depends upon whether or not EHC is caused by tumor formation. A tumor or cholestasis isoenzyme could lead to a high ISO-2 fraction of AA and GGT.

6802 DIAGNOSTIC PROBLEMS OF COMMON BILE DUCT CYSTS IN CHILDREN.

(Ger.) Gudowski, G.; Reuter, G. (Stadt. Klinikum Berlin-Buch, 1115 Berlin-Buch, Karower Strasse 11, E. Germany). *Kinderaerztl. Prax.* 43(12):545-549; 1975.

Two case histories of idiopathic choledochus cysts are presented, and the literature of cystic management is reviewed. A 1.5-yr-old girl with an unremarkable family history presented with transient episodes of dyspepsia, hepatosplenomegaly, elevated α_2 and β globulins, and depressed gammaglobulin from the second postnatal month. Chronic active hepatitis was refractory to prednisone, azathioprine, and D-penicillinamine. At 1.5 yr, increased bilirubin, alkaline phosphatase, and cholesterol with scintigraphic evidence of obstructive disease led to laparotomy. The cysts nearly filled the entire peritoneal space, with gross displacement of the viscera. A 2.5-cm, stenosed residue of the choledochus extended from cyst to the duodenum. Cholecystectomy, with resection of the cystic area as far as the opening of both hepatic ducts, and anastomosis of the cystic residue in the duodenum were performed. Recovery was uneventful. A 5-yr-old girl, who had infectious hepatitis at 1-2 yr, presented with severe right epigastric pain. All hepatobiliary and gastrointestinal studies were negative. Laparotomy found a bile-filled cyst in the bile duct region, with duodenal and adjacent tissue adhesions. A choledochoduodenostomy was performed, and the patient's recovery was uneventful. Idiopathic choledochus cyst is a sex-linked, congenital dilation of the common bile duct. The triad, epigastric tumor, icterus, and abdominal pains are pathognomic for idiopathic choledochus cysts; the therapy is always surgery.

6803 CLINICAL OBSERVATIONS ON THE BILIARY SYSTEM IN CYSTIC FIBROSIS. (Eng.) Isenberg, J. N.; L'Heureux, P. R.; Warwick, W. J.; Sharp. H. L. (Univ. Minnesota Sch. Medicine, Minneapolis, MN 55455). *Am. J. Gastroenterol.* 65(2):134-141; 1976.

Roentgenographic abnormalities of the extrahepatic biliary tree and the lack of correlation with intrahepatic biliary fibrosis were studied in 66 cystic fibrosis patients. Serum gamma glutamyl transpeptidase (GGT) levels were also studied. Each patient was given a single dose of iopanoic acid (.15 g/kg) on 2 consecutive days, and an AP roentgenogram was taken. If visualization was not achieved, the patient was immediately infused with iodipamide (0.5 cm^3/kg), and roentgenograms of the right upper quadrant were taken at 20-min intervals. Percutaneous liver biopsies were performed in 56 patients, and serum was taken from 61 and assayed for GGT activity. A total of 70 cholecystographic evaluations were made. Of the 66 patients, the gallbladder was not visualized in 22 after oral contrast, and i.v. cholangiography had to be used. Six of the 22 (27.3%) had anatomically normal gallbladders. Of the remaining 16, visualization was achieved in 8, and demonstrated microgallbladder, structural abnormalities, and calculi were demonstrated in 5, 2, and 1, resp. No visualization was achieved in eight patients. In contrast, there were only eight anatomically abnormal gallbladders in the 44 patients given successful oral cholecystography. Of the biopsies, only 22 (39.3%) showed no pathology. Twenty-one (37.5%) showed changes in the portal triads, indicative of multifocal biliary cirrhosis, and 10 of these had abnormal cholangiograms (47.6%). Thirteen specimens (23.2%) showed mild to severe fatty changes. Of the 22 patients with normal biopsies, 7 had abnormal gallbladders (31.8%). Focal biliary pathology occurred in 11 of 23 men biopsied (47.8%), and in 10 of 33 women (30.3%). Women had fatty metamorphosis more often (30.3%) than did the men (13%). Of the 61 patients tested for GGT, 52 also had biopsies taken. Only 13 of the biopsy-proven patients with multifocal biliary cirrhosis had elevations of serum GGT (65%). GGT levels were also elevated in 3 of 11 patients with fatty changes in whom enzyme levels were measured. Seven of the 9 women with multifocal biliary cirrhosis had elevated levels (77.8%), compared to only 6 of 11 men (54.5%). It is concluded that liver biopsy is preferred to serum GGT levels in determining whether a cystic fibrosis patient is developing focal biliary cirrhosis.

6804 CHOLECYSTOENTERIC FISTULAS: SIGNIFICANCE AND RADIOGRAPHIC DIAGNOSIS. (Eng.) Balthazar, E. J.; Gurkin, S. (New York Medical Coll., 1901 First Ave., New York, NY 10029). *Am. J. Gastroenterol.* 65(2):168-173; 1976.

The etiology and pathogenesis of cholecystoenteric fistulas occurring in 12 patients without small bowel obstruction are reviewed. Gallbladder fistulas can be divided into two groups: acute and transitory fistulas associated with obstruction of the cystic duct are seen in patients with typical episodes of acute cholecystitis. Most of these fistulas disappear rapidly *in vivo*. Chronic, functioning, and permanent fistulas are detected in patients with minimal or unrelated symptoms and are accompanied by common duct obstruction. Six case reports are presented, two of which illustrate the two respective types of fistula. In the first patient, a 61-yr-old man who had undergone abdominoperineal resection for rectal carcinoma, an initial upper gastrointestinal examination showed a large extrinsic mass compressing the duodenum, representing a distended gallbladder. After the patients' symptoms (right upper quadrant pain and fever) subsided, a follow-up examination demonstrated a small, almost closed fistulous tract. Upper gastrointestinal examination in the second patient, a 69-yr-old woman, who had been operated on for a gallstone ileus 6 yr previously, revealed a cholecystoduodenal fistula, visualized with a contracted gallbladder. Failure of healing with permanent maintenance of such a communication suggested the presence of a functioning fistula associated with obstruction of the common duct. In all 12 cases, p.o. or i.v. cholangiograms failed to visualize the gallbladder; this may be explained by the fact that bile flows directly through the fistulous tract into the duodenum, making the gallbladder unable to retain contrast material.

6805 STRATIFICATION OF BILE IN GALLBLADDER AND GALLSTONE FORMATION. (Eng.) Nakayama, F.; van der Linden, W. (Kyushu Univ. Faculty Medicine, Fukuoka, Japan). *Surg. Gynecol. Obstet.* 141(4): 587-590; 1975.

Methods to express the state of cholesterol saturation in bile, including triangular coordinate plotting, lithogenic index, and cholesterol saturation index, were used to assess the significance of stratified layers of bile present in the gallbladder in gallstone formation. Bile samples were aspirated from 11 patients during surgery for uncomplicated gallstone disease from the upper, middle, and lower layers of the gallbladder. In five of the patients, the most concentrated bile was in the lower layer (corresponding to the infundibulum). In five, the middle layer (corpus) contained the most concentrated bile. In one patient, the upper layer (fundus) contained the most concentrated bile. The mean lithogenic index went from 1.01 for the least concentrated layer to 0.96 for the most concentrated layer. The mean cholesterol saturation index went from 131.7 in the least concentrated layer to 123.1 in the most concentrated layer. The relative deoxycholic acid concentration went from a mean of 24.1 to 26.0 in the least and most concentrated layers, resp. The concentrating ability of the gallbladder differed for each bile constituent, bile salts being the most concentrated, followed by phospholipids and cholesterol. It is suggested that the gallbladder has a selective absorption process.

6806 HEPATIC MEGACHOLEDOCHUS WITHOUT OBSTRUCTION. (Fre.) Salembier, Y. (69, rue de la Louviere, 59000 Lille, France). *Lille Med.* 20(9):811-813; 1975.

An enlarged hepatic bile duct (megacholedochus) without any evidence of blockage or odditis appears to be a rare condition (0.16% of surgical cases), probably of congenital origin. Eleven cases are reported (9 women and 2 men; average age, 57 yr), 10 of whom had an associated lithiasis of the gallbladder. In five cases, the dilation of the duct was disclosed by x-ray prior to operation. The gallbladder contained a single stone the size of a pea in five instances, and in the other instances, the stones were multiple. A cholecystectomy was performed on all 11 patients; in 6 cases, a transcystic drain was left in place thereby confirming the diagnosis of an absence of obstruction. In one case, a choledochojejunostomy was performed. Of the 11 cases, 8 were diagnosed definitely as unobstructed hepatic duct dilation (hepatic bile duct uniformly dilated to at least 15 mm and no stones present in duct, nondilated gallbladder preventing passage of calculi, bile duct pressure normal or low, and cholangiography revealing homogeneity of contrast medium and rapid passage of medium into duodenum associated with a normal sphincter without intrahepatic reflux) and 3 cases were probable (slightly enlarged gallbladder but not enough to allow passage of calculi, no sign of odditis, and low bile duct pressure). The diagnosis must be differentiated from an odditis, which is characterized by high bile duct pressure, and, usually, less dilation of the duct.

6807 SPONTANEOUS RUPTURE OF THE COMMON BILE DUCT. (Eng.) Spira, I. A. (Beth Israel Medical Center, 10 Nathan D. Perlman Place, New York, NY 10003). *Ann. Surg.* 183(4):433-435; 1976.

The rare case of a patient with spontaneous rupture of the common bile duct is presented. The patient, a 59-yr-old man, had been hospitalized for the treatment of a left-sided pneumothorax. The recurrence of pneumothorax following treatment with an intercostal chest tube and the failure of the lung to fully reexpand after the recurrence necessitated a left thoracotomy and a left upper lobectomy. When the patient had initially presented with symptoms of pneumothorax, the liver was found to be firm and palpable. After the thoracotomy, the patient's liver function tests were abnormal, and he became jaundiced. On the 15th postoperative day, he experienced severe abdominal pain associated with vomiting. At laparotomy, a large amount of free bile was present in the peritoneal cavity. The gallbladder was collapsed, and at the junction of the cyctic duct with the common hepatic duct there was a ragged perforation in the common bile duct about 0.5 cm in diameter. Histologic examination of the edge of the perforation revealed the loss of epithelium and evidence of acute and chronic inflammation. After the insertion of a T-tube into the common duct and lavage of the peritoneal cavity with saline, the patient's condition improved. At a second laparotomy, a 3.5-cm villous tumor was found on the medial duodenal wall overlying the ampulla of Vater. The tumor was excised, a cholecystectomy was performed, and a Roux-en-Y choledochojejunostomy was created. Three small calculi were found in the gallbladder. The patient made an uneventful recovery. Histological examination of the tumor revealed the typical appearance of villous adenoma at the periphery, but the central portion showed invasive adenocarcinoma. The authors conclude that three factors were responsible for the rupture of the common bile duct: the raised intraductal pressure due to the tumor at the distal end, the presence of gallstones, and the presence of inflammation.

6808 SPHINCTEROTOMY OF ODDI'S SPHINCTER: REPORT OF 250 CASES. (Fre.) Lataste, J.; Guegan, Y. (Hopital Intercommunal de Creteil, Creteil, France). *J. Chir. (Paris)* 108(4):307-320; 1974.

Data on a series of 250 sphincterotomies (184 women and 66 men; average age, 56 yr) are reported. The sphincterotomy was the primary surgery in 196 cases and secondary to another biliary or pancreatic procedure in 54 cases. In 164 cases, the sphincterotomy was necessary because of stenosis of the sphincter of Oddi, blocking calculi, or a blocked Wirsung canal. The procedure was elective in 111 cases to remove calculi or bile sediment remaining after choledochotomy, to explore the lower bile duct in cases where diagnosis was uncertain, or to ensure complete drainage of biliary or pancreatic ducts. In the remaining 29 cases, the sphincterotomy was considered to be a safety measure to improve biliary drainage when ducts appeared normal or a repeat surgical intervention for residual common bile duct pathology. Acute pancreatitis resulted in death of 4/17 patients with intra-abdominal complications. There were 19 cases of general complications such as cardiovascular accidents or thromboembolisms; death resulted in 9 cases. Late complications occurred in 19 patients including 7 cases of cholangitis, 4 of which were not due to obstruction. Since atonic stasis in the common bile duct plays a major role in late complications, a gastro-biliary anastomosis is recommended when bile duct is dilated and atonic. Over-all late results were judged as good to excellent, 61.2%; passable or poor, 11.2%; and deaths, 8.8%. In a series of 200 choledochoduodenostomies, over-all results were more favorable. The indications for sphincterotomy should be clearly defined before surgery.

6809 THE PATHOLOGY OF THE INFUNDIBULUM OF THE SPHINCTER OF ODDI. (Fre.) Yvergneaux, J. P.; Bauwens, E.; Yvergneaux, E.; Barraya, L.; Pujol-Soler, R. (Service de Chirurgie a Gand, Universite de Gand, Belgium). *Acta Gastroenterol. Belg.* 38(3/4):137-155; 1975.

Disorders of the infundibulum of the sphincter of Oddi (the muscular canal between the upper sphincter and the papilla) identified by radiomanometric and cholangiographic studies of 1151 patients undergoing surgery are described. Except for a small carcinoma clearly originating in the infundibulum, all cases of malignant lesions were excluded from the study. In several instances, postoperative follow-up was accomplished using cinematography or seriography. The studies indicate that the presence of calculi in the infundibulum without adjacent papillary pathology (calculi and benign stenosis of the sphincter of Oddi) did not alter manometric measurements in the common bile duct. It is observed that the papilla is a strong sphincter whereas the infundibulum has remarkable plasticity. The radiomanometric studies revealed alterations in the consistency of the bile or the presence of blood in the infundibulum. Usually, a chronic obstacle such as calculi or stenosis was responsible for bile stasis; however, infrequently (1.5%), the altered bile or blood was the result of the emptying of a cholecyst or gangrenous cholecystitis. Diverticuli and benign tumors of the infundibulum and papilla are described and discussed. Careful study of the anatomy and pathology of the sphincter of Oddi can prevent needless duodenotomies, sphincterotomies, or reintervention for residual or recurrent calculi.

GENERAL

6832 GASTRIC METASTASIS FROM BREAST CARCINOMA: EMERGENCY SNARE-ECTOMY FOR CONTROL OF HEMORRHAGE. (Eng.) Dupas, J. L.; Delamarre, J.; Marti, R.; Capron, J. P.; Lorriaux, A. (Centre Hospitalier Universitaire, Place Victor Pauchet, F-80030 Amiens, France). *Endoscopy* 8(1):35-37; 1976.

The case of a 65-yr-old woman, in whom a bleeding gastric metastasis from a breast carcinoma was successfully removed with a high-frequency diathermy loop passed through a fibroscope, is presented. The patient presented with melena. Seven years previously, a left radical mastectomy had been performed for carcinoma, and 1 yr prior to admission, metastases were detected in the lungs and bones. An upper gastrointestinal series revealed a single filling defect in the fundus. A double contrast x-ray examination of the stomach showed a typical "target" appearance of the ulcerated lesion; this was confirmed by an endoscopy. Emergency gastroscopy was performed because of massive hematemesis. A high-frequency diathermy loop was passed through the panendoscope and placed around the tumor. The base of the lesion was easily transected, and all bleeding stopped. The resected portion of the lesion was then sucked against the tip of the endoscope and removed. Histological examination revealed a poorly differentiated glandular carcinoma, forming irregular, small acini. The superficial glandular epithelium was normal. Electrocauterization in the emergency treatment of patients bleeding from an ulcerated tumor can prevent the risks of abdominal surgery and allow prolonged survival.

6833 TUBERCULOUS BOWEL PERFORATIONS. (Eng.) Asraf, S. M.; Mital, R. N.; Prakash, A. (Dept. Surg., Maulana Azad Medical Coll., New Delhi, India). *Am. J. Proctol.* 26(6):47-51; 1975.

Because of the increasing incidence of tuberculous bowel perforations during antimicrobial therapy, the incidence, clinical features, pathology, management, mortality, and morbidity of this lesion were investigated in 240 patients with abdominal tuberculosis, and the literature is reviewed. In comparison with previous studies that reported an incidence of 0-10.5%, the incidence in this study was 1.25% (2 men and 1 woman, 18-28 yr). Chronic abdominal pain and abdominal distention and tenderness occurred in all three patients. One patient was already on antitubercular treatment and had a history of subacute obstruction. Vomiting occurred in one patient, and constipation occurred in the other two cases. Two perforations occurred in the ileum in one patient, and a double layer closure was performed. In the second patient, a 0.5-cm perforation occurred over an ileal stricture, 18 inches from the ileocecal region; there was an associated jejunal stricture. Resection of the stricture bearing the perforation and an enteroenterostomy bypass for the jejunal stricture were performed. A 1-cm perforation occurred in the terminal ileum of the third patient, 4 inches proximal to the ileocecal region. Enlarged lymph nodes were noted in the mesentery. Closure of the perforation with an ileotransverse colostomy was performed. One patient died of toxemia and shock. One patient had mild wound sepsis, and the third patient recovered after prolonged postoperative ileus, thrombophlebitis, septicemia, and wound disruption.

6874 THE LYMPHOKINE EOSINOPHIL STIMULATION PROMOTER AND HUMAN Schistosomiasis mansoni. (Eng.) Kazura, J. W.; Mahmoud, A. A. F.; Karb, K. S.; Warren, K. S. (Dept. Medicine, Case Western Reserve Univ., Cleveland, OH 44106). *J. Infect. Dis.* 132(6):702-706; 1975.

An *in vitro* assay for a lymphokine eosinophil stimulation promoter (ESP) is described in terms of its potential for the diagnosis of *Schistosomiasis mansoni*. Peripheral eosinophils from seven patients with *S. mansoni* infection were specifically induced to migrate on incubation with soluble egg antigen (SEA) in concentrations ranging from 0.1-10 µg, with the peak effect occurring with 10 µg of SEA. SEA had no effect on eosinophils from four individuals without schistosomiasis. Incubation of purified human peripheral lymphocytes from eight *S. mansoni* patients with SEA resulted in the secretion of ESP, which enhanced the migration of purified eosinophils from patients with or without infection. Lymphocytes from four normal controls did not produce ESP when incubated with SEA. This *in vitro* assay may provide a useful tool for the diagnosis of *S. mansoni* infection. The reliability and reproducibility of the ESP assay makes it a useful *in vitro* correlate of delayed hypersensitivity that can be performed easily with human target cells.

6905 ISOLATION AND KINETIC CHARACTERISTICS OF MUCOSAL LYMPHOCYTES IN CROHN'S DISEASE. (Eng.) Clancy, R. (Host Resistance Programme, McMaster Univ., Hamilton, Ontario, Canada L8S 4J9). *Gastroenterology* 70(2):177-180; 1976.

A technique for obtaining viable lymphocytes from human intestinal mucosa was developed to characterize the kinetics of DNA synthesis in the mucosal lymphocytes of the normal and diseased intestine. Single cell suspensions of lymphocytes were derived from the small intestinal mucosa of nine patients with Crohn's disease and from four control patients with normal mucosa, and short-term cultures were established. Cells were separated from mucus by shaking in a vortex mixer, followed by centrifugation at 1,500 rpm for 5 min. The supernatant was removed, and cells and the remaining mucus were resuspended in medium; the process was repeated (4-6 times) until all mucus was dissipated. The cell button was resuspended in medium (RPMI 1640 containing 3% bovine serum albumin), and the cell suspension was passed through siliconized glass bead columns. In comparison to controls, high rates of DNA synthesis were found in 72-hr cultures of the mucosal lymphocytes from all but one patient with Crohn's disease. These rates correlated with the appearance of numerous transformed blast cells in terminated cultures. Lymphocytes from normal and abnormal gut mucosa were stimulated by phytohemagglutinin-P, except in some patients with Crohn's disease with high rates of "spontaneous" DNA synthesis. The isolation and culture of human gut mucosal lymphocytes by a simple preparative technique will enable the direct study of lymphocyte function in both normal and diseased gut mucosa.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-31
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1978.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

6910 THE EFFECT OF ETHANOL APPLIED DURING GESTATION ON THE MITOCHONDRIA OF THE HEPATIC CELLS OF PUPS. (Eng.) Beskid, M.; Majdecki, T.; Skladzinski, J. (Medical Center Postgraduate Education, ul. Marymoncka 99/103, 01-813 Warsaw, Poland). *Folia Histochem. Cytochem. (Krakow)* 13(3/4):175-180; 1975.

Because previous studies have shown that ethanol causes marked changes in the activities of hepatic oxidative enzymes, the hepatocytic mitochondria of five pups whose mothers had received ethanol throughout the gestation period were examined by electron microscopy. The pregnant dogs had received 250 ml of 25% ethanol in their food twice daily for 20 days (from the first to the last day of gestation). In comparison to controls, mitochondria of the test pups were abnormally elongated, and some assumed monstrous shapes. The abnormal mitochondria contained increased numbers of cristae, which varied in length and arrangement. In addition, the mitochondria of the experimental animals were more densely arranged within the hepatocytes. The parenchymal cells of these animals contained increased numbers of lysosome-like bodies, which occurred in the proximity of the Golgi apparatus. The results indicate that ethanol not only disturbs the metabolism of the hepatocyte mitochondria of animals directly exposed to it, but also that its effects can be transmitted *in utero*.

6911 THE EPITHELIAL SURFACE OF THE MONKEY GASTROINTESTINAL TRACT: A SCANNING ELECTRON-MICROSCOPIC STUDY. (Eng.) Burke, J. A.; Holland, P. (Univ. Kentucky Coll. Medicine, Lexington, KY 40506). *Digestion* 14(1):68-76; 1976.

Scanning electron microscopy was used to investigate the surface topography of individual gastrointestinal cells, the relative distribution of various cell types, and cell orientation of the gastrointestinal tract of six normal monkeys. The surface of the epithelial cells lining the esophagus was characterized by a prominent network of circular and linear cytoplasmic microplications. In contrast, the mucous cells of the stomach were seen to be covered by well-spaced, stub-like microvilli of varying diameters. The surface of the columnar absorptive cells of the small intestine differed from that of the large intestine. Although the absorptive surface of the columnar cells in both segments was covered by microvilli, the colonic microvilli were less abundant, permitting visualization of the entire length of some of the elongated microvillous projections. The epithelial surfaces of Peyer's patches revealed a cell type different from those covering adjacent villi; these M cells were covered by a sparse population of stub-like and finger-like microvilli. Regular repetitious polygonal units demarcated by deep furrows were observed in the colonic mucosa, prepared by air drying from acetone, but not when the mucosa was prepared by critical point drying; this suggests that they appear as a result of tissue shrinkage. The observations allowed the characterization of the surface architecture of the epithelial cells from segment to segment and defined the criteria for the identification of an isolated segment on the basis of cell surface morphology alone.

6912 BIOCHEMICAL AND MORPHOLOGICAL STUDIES ON HUMAN JEJUNAL MUCOSA MAINTAINED IN CULTURE. (Eng.) L'Hirondel, C.; Doe, W. F.; Peters, T. J. (Royal Postgraduate Medical Sch., Du Cane Road, London W12 OHS, England). *Clin. Sci. Mol. Med.* 50(5): 425-429; 1976.

Human jejunal mucosa maintained in culture using a wire-mesh support plus roller-tube technique was studied biochemically and morphologically. Biopsy specimens were taken from 11 control subjects and from 5 patients with untreated celiac disease. During culture, the villi of the normal mucosa tended to be broader and reduced in height, but the appearance of the celiac mucosa was unchanged. Light microscopy of normal specimens showed normal architecture, with some blunting of villi; in the celiac mucosa, there was an absence of villi and the presence of hypercellular crypt regions and nuclear irregularities in the enterocytes. Radioautographs were prepared after incubation with ^{3}H-leucine (2 μCi). The enterocytes showed evidence of intense protein synthesis, but the immunocytes and interstitial cells were labeled less intensely than the epithelial cells. DNA synthesis was studied by incubation of two normal biopsies with 10 μCi ^{3}H-thymidine. Several crypt cells were labeled without any incorporation into the immunocytes or interstitial cells. The tissue protein and DNA contents fell during culture, but the combined tissue and medium DNA content remained constant. This suggests that this parameter may be used as a reference for enzyme and biochemical studies on cultured intestinal biopsies.

6913 CHANGES IN THE ORGANS OF PIGS IN RESPONSE TO FEEDING FOR THE FIRST 24 H AFTER BIRTH. II. THE DIGESTIVE TRACT. (Eng.) Widdowson, E. M.; Colombo, V. E.; Artavanis, C. A. (Dept. Investigative Medicine, Cambridge Univ., Downing Site, Downing St., Cambridge CB2 1QN, England). *Biol. Neonate* 28(5/6): 272-281; 1976.

The response of the gastrointestinal (GI) tract to food during the first 24 hr after birth was investigated in piglets. The piglets were either sacrificed immediately after birth or fed water for 24 hr, suckled for 24 hr, or suckled for 10 days prior to sacrifice. The entire GI tract was removed at once and weighed. In the suckled piglets, the stomach and small and large intestines gained rapidly during the first 24 hr, more so than during the next 9 days. The large intestine gained 40% in weight and 34% in length in 24 hr. The differences in length of both intestines at birth and 24 hr after suckling were statistically significant ($p<0.001$), as were the differences in weight of the small intestine ($p<0.001$). For weight gain of the stomach and large intestine, $p=0.005$ and 0.01, resp. There was also a concurrent significant increase in grams per centimeter of the small intestine ($p<0.001$). The gains in the jejunum and ileum were greater than those in the duodenum. In the jejunum, both muscle and mucosa increased in weight, but the mucosa more than the muscle, and there was an increased amount of protein in it. Some may have been colostral protein in the process of being absorbed. The lactase and acid phosphatase activities in the jejunal mucosa increased during the first 24 hr in suckled animals, but, because of the large increase in the amount of mucosa and of the protein in it, the enzyme activities (per gram of protein) fell. The increased lactase activity during the first 24 hr was in response to food. The results agree with previous ones showing a fall in enzyme activity that passed from the upper to the middle and lower third of the jejunum in unsuckled newborn animals, but no such fall at 10 days.

6914 ISOLATION OF BILE DUCTS FROM RAT LIVER: TECHNIQUE AND PRELIMINARY ULTRASTRUCTURAL CHARACTERIZATION.

(Eng.) Oda, M.; Yousef, I. M.; Phillips, M. J. (Dept. Pathology, Toronto General Hosp., Toronto, Ontario, M5G 1L5, Canada). *Exp. Mol. Pathol.* 23(2):214-219; 1975.

A bile duct-containing fraction was isolated from the liver of male Wistar rats, and a preliminary electron microscopic characterization was made using conventional (glutaraldehyde and osmium tetroxide) and ruthenium red (RR) staining techniques. For comparison, the livers from five rats were stained *in vivo*, i.e., the liver was perfused with RR stain via a catheter inserted into the portal vein. The conventional stain showed that the bile duct pellet isolated from the liver homogenates contained a large number of intact bile ducts, but that the contaminating components of the pellet were disintegrated and fragmented. The bile ducts were formed by four or more biliary epithelial cells situated around a central lumen and surrounded by a basement membrane. The cell membranes were intact, and the luminal surface was covered with microvilli. A granular cytoplasmic deposit was found and, frequently, an intact basement membrane surrounded the bile ducts. In the RR-stained *in vivo* preparations, the fine structure of the bile ducts was similar to that seen with the conventionally stained *in vitro* preparations. The stain did not penetrate the basement membrane around the bile ducts, and no staining of the biliary epithelial occurred. In the isolated RR preparations, there were similar findings; in partially disrupted ducts, RR entered the biliary cells and clearly demonstrated the surface coat on the luminal surface of biliary epithelial cells, including the surface of microvilli. Sharp visualization of intracellular microfilaments was also obtained. The dense RR-positive microfilamentous network corresponded to the diffuse granular material observed with the conventional stain.

6915 THE INFLUENCE OF HISTAMINE ON EPITHELIAL CELL PROLIFERATION IN THE JEJUNUM OF THE RAT.

(Eng.) Tutton, P. J. M. (Dept. Anatomy, Monash Univ., Clayton, 3168, Victoria, Australia). *Clin. Exp. Pharmacol. Physiol.* 3(4):369-373; 1976.

The influence of small doses of histamine and histamine H_1- and H_2-receptor blockage, and of histamine depletion on the proliferation of jejunal epithelial cells was studied in male Sprague-Dawley rats. Mitotic rates were measured in the bases of the crypts of Lieberkuhn over a 4-hr period after an i.p. injection of 0.1 mg/kg histamine acid phosphate. Four rats were treated with the histamine H_1-receptor blocking agent, mepyramine (2.5 mg/kg) and histamine, and four others were treated with the histamine H_2-receptor blocking agent, metiamide (0.5 mg/kg) and histamine. Six rats received 200 mg/kg DL-α-methylhistidine dihydrochloride at 0800 and 1200 hr, which caused a rapid depletion of tissue stores of histamine. Tissue for a mitotic rate study was taken at 1200-1600 hr. The control mitotic rate in the crypts was 0.49 mitoses/cell/hr. In rats treated with histamine alone, the mitotic rate was 0.079 mitoses/cell/hr, a significantly higher value ($p<0.001$). The rats given mepyramine and histamine had a mitotic rate of 0.085 mitoses/cell/hr. In rats given metiamide and histamine, the mitotic rate was 0.045 mitoses/cell/hr, significantly lower than that in rats given histamine alone ($p<0.05$), and not significantly different from control values. In the rats in which endogenous histamine synthesis was blocked, the rate was 0.043 mitoses/cell/hr. The results suggest that proliferation of epithelial cells in the crypts of Lieberkuhn in rats can be stimulated by histamine and that histamine exerts its influence as an H_2-receptor.

6916 THE FINE STRUCTURE AND LOCALIZATION OF ALKALINE PHOSPHATASE ACTIVITY OF THE SMALL INTESTINAL EPITHELIUM IN THE POSTNATAL DEVELOPING RAT.

(Eng.) Ono, K. (Dept. Anatomy, Sch. Medicine, Iwate Medical Univ., Morioka 020, Japan). *Acta Histochem.* 52:117-133; 1975.

The morphological structure of and the development of alkaline phosphatase (AP) activity in the small intestine of newborn rats were investigated by light and electron microscopy. Electron microscopy showed the presence of apical small vacuoles and tubules, with a well-developed microvillous border, in the duodenum on the day of birth. The cytological features of the jejunal epithelium were similar. In the ileum of 5-day-old-rats, 49% of the small intestine contained cells with a supranuclear vacuole. This figure dropped to 25% at 15 days, and in a 23-day specimen, there were no cells containing a supranuclear vacuole, apical vacuoles, or tubules. AP activity of the duodenal and jejunal epithelial cells was observed on the microvilli, apical vacuoles and tubules, and the tubular invagination until the 14th day. After the 15th day, the enzyme activity was localized on the microvillous membrane. This cytochemical pattern in the jejunum showed no change with age. Around the 23rd day, AP activity of the duodenal epithelium was observed in the same sites as those in the full-grown rat; i.e., on the microvilli, the lateral cell membrane, and the Golgi apparatus. During suckling, AP activity in the ileal cells was seen in the microvillous membrane, lateral cell membrane, apical tubulovacuolar system, and the supranuclear vacuole. At weaning however, the last two structures disappear, and all absorptive cells in the epithelium are free of reaction products as in the adult rat. The total amount of AP is higher in the ileal epithelium than the jejunal epithelium. The results show that the tubulovacuolar system and the supranuclear vacuole are important cytological features of protein absorption in the small intestinal epithelium during suckling.

6917 REGULAR STRUCTURES IN UNIT MEMBRANES. III. FURTHER OBSERVATIONS ON THE PARTICULATE COMPONENT OF THE SUCKLING RAT ILEUM ENDOCYTIC MEMBRANE COMPLEX. (Eng.) Robertson, J. D.; Knutton, S.; Limbrick, A. R.; Jakoi, E. R.; Zampighi, G. (Dept. Anatomy, Duke Univ. Sch. Medicine, Durham, NC 27710). *J. Cell Biol.* 70(1):112-122; 1976.

The morphology of the particles decorating the lumenal surfaces of membranes of the endocytic complex of the epithelial cells from the suckling rat ileum is described. The particles each measure about 7.5 nm across and look like the capital letter H in frontal view. They consist of n-acetyl-β-glucosaminidase (NAG), and they are arranged in rows, with the symmetrical lateral bars spaced about 14.5 nm apart. A purified preparation of these membranes was studied by electron microscopy using thin sectioning, negative stain, Markham translation, and optical-diffraction computer-image-reconstruction methods. The individual particles can be seen in profile when dried in a pool of negative stain. They appear either triangular or diamond-shaped. If triangular, they appear to consist of three domains at the corners of an equilateral triangle, one side of which is parallel to the membrane surface but separated from it by a dense band of negative stain about 2 nm thick that runs along the membrane surface. A fourth domain is sometimes visible within this dense band, giving a diamond-shaped figure. This fourth domain connects the particle to the membrane. Thus, each H-shaped particle is a double structure, with each half looking like a diamond in profile. Each H-shaped particle is believed to consist of either two or four molecules of NAG. NAG is now sufficiently characterized to allow it to be singled out from other enzymes and identified in negatively stained preparations.

6918 PROLIFERATIVE CAPABILITY OF PARIETAL AND ZYMOGEN CELLS. (Eng.) Chen, K. Y.; Withers, H. R. (Dept. Medical Res., Natl. Defense Medical Center, Veterans General Hosp., Taipei, Taiwan, Republic of China). *J. Anat.* 120(3):421-432; 1975.

The proliferative capability of parietal and zymogen cells was investigated in 6- to 8-week-old male C3Hf/Bu mice. The mice were killed and studied from 30 min to 30 days after i.p. injection of ^{3}H-thymidine (50 μCi/mouse). Labeling of parietal and zymogen cells was observed in autoradiographic histological specimens. There were 590 ± 22 gastric glands per circumference at the body of the stomach. The number of parietal cells was 16.2 (14.0-18.4) per gland or 9,600 per circumference. There were 11.4 (9.4-13.7) zymogen cells per gland or 6,700 per circumference. Two labeled immature parietal cells per circumference were seen 30 min after injection, equivalent to a ratio of 1:5,000; more mature labeled cells were seen later, at times up to 30 days. There was evidence for proliferation during maturation and downward migration of these cells toward the body and the lower part of the gastric gland. An average of 2.6 zymogen cells per circumference, or 1:2,500, was labeled. Although most zymogen cells were not proliferating, cells entered the proliferating cycle at random. The data support earlier evidence that immature parietal cells constantly supply mature parietal cells through migration from a proliferative zone. Whether the parietal cells are derived from the same stem cell compartment as surface epithelium cells is unclear. Based on these findings and the radiation responses of both parietal and zymogen cells, it is postulated that they form part of a slow renewal system.

6919 ELECTRON MICROSCOPE STUDIES OF EXPERIMENTAL Entamoeba histolytica INFECTION IN THE GUINEA PIG: II. EARLY CELLULAR AND VASCULAR CHANGES ACCOMPANYING INVASION OF THE LAMINA PROPRIA. (Eng.) Takeuchi, A.; Phillips, B. P. (Walter Reed Army Inst. Res., Washington, DC 20012). *Virchows Arch. [Zellpathol.]* 20(1):1-13; 1976.

ABSORPTION - EXCRETION - TRANSPORT

6925 NEW CHARACTERISTICS OF HARMALINE INHIBITION OF INTESTINAL TRANSPORT SYSTEMS. (Eng.)

Sepulveda, F. V.; Robinson, J. W. L. (Departement de Chirurgie Experimentale, Hopital Cantonal Universitaire, CH-1011 Lausanne, Switzerland). *Naunyn Schmiedebergs Arch. Pharmacol.* 291(2):201-212; 1975.

The mechanism of harmaline on intestinal transport was investigated *in vivo* in guinea pigs and dogs, and its effect was compared with related psychotomimetic compounds. Rings of guinea pig small intestine were incubated with 1 mM phenylalanine and several concentrations of harmaline. The lowest concentration having a significant inhibitory effect was 0.1 mM. The drug (at 4 mM) inhibited the unidirectional mucosal-to-serosal (M-S) flux of phenylalanine (from around 300 to 35 nmol/cm^2/hr), but only when it was added to the solution bathing the mucosal surface. The M-S flux of Na was similarly reduced. Ion and water absorption in the perfused dog intestine *in vivo* was also diminished by harmaline. The effects of several other psychotropic indole analogs were measured. The actions of harmine and harmalol were similar to that of harmaline, despite their different lipid solubilities. N:N-dimethyltryptamine was equally inhibitory, but serotonin was inactive. Mescaline and lysergic acid diethylamide inhibited phenylalanine transport, but to a much lesser extent than harmaline. These results support the hypothesis of the rapid onset of harmaline inhibition of Na-dependent uptake mechanisms, and they indicate that harmaline interacts with the Na site of nonelectrolyte carrier complexes.

6926 INHIBITION OF INTESTINAL AMINO ACID ABSORPTION BY UNCONJUGATED BILE SALT IN VIVO.

(Eng.) Burke, V.; Gracey, M.; Thomas, J.; Malajczuk, A. (Princess Margaret Children's Medical Res. Foundation, Perth, Western Australia). *Aust. N.Z. J. Med.* 5(5):430-432; 1975.

The possibility that unconjugated bile salts inhibit the absorption of the products of protein digestion was studied *in vivo* in female Wistar rats. The animals were perfused via the proximal jejunum with a solution containing 10 mM unlabeled L-leucine, L-proline, L-lysine, L-glycine or glycyl-glycine or 2.5 mM unlabeled L-tyrosine, with the addition of 0.67 μCi/ml of the appropriate ^{14}C-labeled amino acid. The initial intestinal absorption of the five amino acids (mean=0.61, 0.78, 0.56, 0.70, 0.083, and 2.8 μmol substrate absorbed/cm/hr for L-lysine, L-proline, L-glycine, L-leucine, L-tyrosine, and glycyl-glycine, resp.) was significantly inhibited when 1 mM deoxycholate was added to the perfusion (0.19, 0.59, 0.24, 0.33, 0.039, and 0.8 μmol/cm/hr, resp.). These results are similar to the effect of unconjugated bile salts on intestinal sugar transport. It seems likely that inhibition of the intestinal absorption of amino acids and dipeptides may contribute to the hypoproteinemia associated with bacterial contamination of the upper gut.

6927 INHIBITION OF INTESTINAL ABSORPTION OF L-PHENYLALANINE IN VIVO BY L-ALANINE. (Eng.)

Wapnir, R. A.; Lifshitz, F. (North Shore Univ. Hosp., Manhasset, NY 11030). *Proc. Soc. Exp. Biol. Med.* 152(3):307-311; 1976.

In a search for alternative approaches to the established dietary treatment of phenylketonuria, the mode of action and kinetics of L-alanine (L-Ala) inhibition on L-phenylalanine (L-Phe) intestinal transport was studied in an *in vivo* system. Isolated, 20-cm open segments of the upper jejunum in anesthetized female Wistar rats were used. The absorption rates of L-Phe, when perfused either at 1 or 2 mM, were affected by the simultaneous presence of L-Ala only when the ratio of L-Ala to L-Phe was 10 to 1 or higher. The presence of a 20 to 1 molar ratio decreased the L-Phe absorption rates by 27.8% for a 1 mM perfusate and by 43.7% in a 2 mM L-Phe solution. A V versus V/S plot, where V is the absorption for different concentrations of the substrate L-Phe (S), showed that the inhibition was noncompetitive, and the same conclusion was obtained from a Lineweaver-Burk plot. The mean intestinal absorption rates of 2 mM L-lysine, L-histidine, and L-methionine were also significantly inhibited by 40 mM L-Ala (11.76, 9.16, and 10.23 nmol/min x cm, resp., without L-Ala; 6.92, 4.79, and 8.41 nmol/min x cm, resp., with L-Ala). The same concentration of L-Ala had no effect on the absorption of 2 mM (L-) arginine, leucine, isoleucine, valine, tryptophan, threonine, or typrosine. These results indicate that the common transport mechanism for neutral amino acids is also operative for positively charged amino acids and that the proportion of the translocation load for these substances is based toward the common carrier. The addition of 40 mM galactose alone produced no significant effect on the rate of 2 mM L-Phe absorption; together with 40 mM L-Ala, however, galactose produced an additive effect and a reduction of the absorption rate to 48.8% of the baseline value. The results are consistent with the presence of two active transport mechanisms for neutral amino acids in the intestinal mucosa: a common one that can be blocked by large concentrations of L-Ala and a specific site or carrier that is not affected by this inhibitor.

6928 CONCENTRATION CHANGES OF BILE ACIDS IN SEQUENTIAL SEGMENTS OF PIGEON INTESTINE AND THEIR RELATION TO BILE ACID ABSORPTION.

(Eng.) Spittell, D.; Vongroven, L. K.; Subbiah, M. T. R. (Mayo Clinic, Rochester, MN 55901). *Biochim. Biophys. Acta* 441(1):32-37; 1976.

The concentration of bile acids in contents from sequential intestinal segments of pigeons was measured to determine the absorption site of bile acids. The nature of bile acids in the various segments, and the fecal excretions of bile acids and sterols following bypass surgery, were also studied in pigeons. Chenodeoxycholic acid was the major bile acid in the duodenum, comprising 78.5% of the total bile acids; this level decreased to 52.7%, 30.6%, and 22.7% in the jejunum, ileum, and colon (cloaca), resp. As the concentration of chenodeoxycholate decreased, the concentration of lithocholic and 7-ketolithocholic acids increased. The concentration of total bile acid was increased from the duodenum to the jejunum and decreased from the jejunum to the colon, indicating rapid reabsorption of bile acids through intestinal transit. When the ratio of the concentration of bile acids to that of nonabsorbable β-sitosterol was examined, it was found that the ratio dropped markedly from the upper jejunum to the lower jejunum (90.1%), while the drop in the ratio from the lower jejunum to the ileum was minimal (8.3%). When the fecal excretion of bile acids and neutral sterols in the early period following ileal bypass (1 month) was compared to the rate in sham-operated pigeons, there was no significant change in the fecal excretion of bile acids and neutral sterols. There was a slight increase in the fecal excretion of total sterols in the bypassed birds, but this was far less than that occurring in mammals. These studies show that in birds, the normal jejunum can absorb significant amounts of bile acids. Under conditions of ileal bypass, the jejunum can maintain normal enterohepatic circulation of bile acids.

6929 ACTIONS OF RICINOLEIC ACID AND STRUCTURALLY RELATED FATTY ACIDS ON THE GASTROINTESTINAL TRACT. II. EFFECTS ON WATER AND ELECTROLYTE ABSORPTION IN VITRO.

(Eng.) Gaginella, T. S.; Stewart, J. J.; Olsen, W. A.; Bass, P. (Sch. Pharmacy, Univ. Wisconsin, 425 N. Charter St., Madison, WI 53706). *J. Pharmacol. Exp. Ther.* 195(2):355-361; 1975.

The hydrophoric activity of ricinoleic acid and a series of structurally related fatty acids was investigated using an everted hamster gut sac technique. In the jejunum, a maximal (77%) inhibition of net water absorption was elicited by 2.0 mM ricinoleate, but 8.0 mM ricinelaidate (the *trans* isomer) was required to produce the same effect. Ricinoleate significantly inhibited net sodium ($p<0.001$) and potassium ($p<0.005$) absorption, but ricinelaidate did not affect the absorption of either ion. Net chloride absorption was decreased by both compounds ($p<0.005$ or greater). Concentrations of oleate greater than 2.0 mM produced a significant inhibition in net water absorption, and maximal inhibition (71.16%) occurred at 8.0 mM. The *trans* isomer of oleate was ineffective. Net water, sodium, and chloride absorption were significantly inhibited by 2.0 mM ricinoleyl alcohol; the initial mean level of water absorption was 78 μl/min/g, and this was reduced to 32 μl/min/g. The methyl ester of ricinoleate (2.0 mM) had no observable effect. Net water, sodium, and chloride absorption were significantly reduced by the *cis*, but not the *trans*, isomer of 2.0 mM linoleate. Although 2.0 mM sodium stearate or 9,10-hydroxystearate produced no significant reductions in electrolyte or water absorption, 2.0 mM 12-hydroxystearate caused significant reductions in sodium, chloride, and water transport ($p<0.05$). In the ileum, 2.0 mM ricinoleate and ricinelaidate produced significant ($p<0.005$) reductions in net water absorption. Both oleate and elaidate (both at 2.0 mM) were ineffective in the ileum. At mucosal concentrations of 2.0 mM, the unsaturated fatty acids had the following rank order of potency on the inhibition of water absorption: ricinoleate ≥ ricinelaidate ≥ linoleate oleate > linelaidate >> elaidate. The results define those portions of the ricinoleic acid molecule required for its effect on water and electrolyte absorption and suggest that classification of this cathartic as an "irritant" or "stimulant" should be reevaluated.

6930 TRANSPORT AND CONJUGATION OF ^{14}C-BILIRUBIN DURING ACUTE AND CHRONIC CHOLESTASIS IN THE CHOLECYSTECTOMIZED DOG.

(Eng.) Bergan, A.; Taksdal, S.; Sander, J. (Surgical Dept. B, Rikshospitalet, Univ. Clinic, Oslo, Norway). *Eur. Surg. Res.* 7(6):355-365; 1975.

The role of the lymphatics in the regurgitation of bilirubin during acute and chronic extrahepatic cholestasis in the dog was studied after i.v. injection of ^{14}C-bilirubin (2.87×10^6 to 1.575×10^8 disintegrations/min). In two dogs subjected to acute biliary obstruction, the bilirubin was rapidly removed from the plasma and was deposited in thoracic duct lymph as labeled bilirubin conjugates. These conjugates were found in the lymph 15 min after injection; they increased to reach a maximum after 1 hr. The total and continuous thoracic duct drainage used prohibited any lymph-to-blood recirculations of radioactive bilirubin. No labeled conjugates were at any time demonstrated in plasma, a result of a biliolymphatic regurgitation. In dogs with chronic biliary obstruction, there was an initial rapid fall in the amount of labeled unconjugated bilirubin in the plasma, followed 2 min later by a rapid reappearance of labeled conjugates that reached a maximum in 1 hr. It is suggested that these conjugates were delivered back into the plasma directly, and not by the lymphatic pathway, as during acute cholestasis. Thus, no specific transport function of the lymph was found. These results show a change in liver cell secretory direction in long-standing cholestasis.

6931 EVIDENCE FOR CARRIER-MEDIATED UPTAKE AND EFFLUX OF SUGARS AT THE SEROSAL SIDE OF THE RAT INTESTINAL MUCOSA IN VITRO.

(Eng.) Bronk, J. R.; Ingham, P. A. (Dept. Biology, Univ. York, York YO1 5DD, England). *J. Physiol. (Lond.)* 255(2): 481-495; 1976.

The bidirectional, transintestinal movement of sugars from the serosal surface of the mucosal cell was examined in male Wistar rats using a modification of the relatively intact everted sac preparation before and after treatment with mercuric chloride. Everted jejunal sacs were incubated for 5, 10, and 15 min in a mucosal mixture of 2 mM D-^{3}H-galactose (D-gal) and 2 mM L-^{14}C-glucose (L-glu). The D-gal/L-glu ratio in the mucosal medium at the start of incubation was 1. At 5, 10, and 15 min, however, it was significantly higher in the serosal layer (8.80, 11.45, 10.19, resp.) than in the mucosal layer (6.53, 7.28, 6.89). The D-gal moved out of the mucosal layer in preference to L-glu. The mediated serosal efflux of galactose was inhibited ($p<0.001$) by 0.5 mM phlorizin on the mucosal side and to some extent ($p<0.01$) by any reduction in the mucosal Na$^+$ concentration (from 25 mM). Both inhibited galactose uptake at the brush border. Serosal efflux of the sugar appeared to be saturated at high concentrations of D-gal. Pretreatment of the sacs with 2 mM mercuric chloride considerably reduced D-gal uptake from the mucosal side (from 8.44 mM, control, to 3.28 mM) but did not affect its efflux relative to L-glu at the serosal side. The D-gal/L-glu ratios change as the sugars pass from one compartment to the next, and they are indicative of the selective transport of one sugar in relation to the other.

6932 STUDIES ON THE TRANSPORT OF ALIPHATIC GLUCOSIDES BY HAMSTER SMALL INTESTINE IN VITRO.

(Eng.) Ramaswamy, K.; Bhattacharyya, B. R.; Crane, R. K. (Dept. Physiology, Coll. Medicine and Dentistry of New Jersey, Rutgers Medical Sch., Piscataway, NJ 08854). *Biochim. Biophys. Acta* 433(1):32-38; 1976.

Eight alkyl D-glucosides were tested *in vitro* as substrates for the Na$^+$-dependent glucose transport system of hamster small intestine. These glucosides have alkyl aglycones of various chain lengths, terminated by a methyl group, a hydroxyl group, or a second glucose unit in glycosidic linkage. Homogenates were prepared from everted segments of small intestines from male hamsters. The amount of glucose liberated by hydrolysis was determined by the glucose oxidase method and was taken as a measure of glucoside transport. With decyl glucoside, maximal uptake occurred at 5 min, at which time an apparent tissue/medium ratio of 7.0 was established. The process of uptake was strongly inhibited (57%) by 2,4-dinitrophenol at 1 mM. Dodecyl glucoside strongly inhibited the uptake of β-methyl glucoside with competitive kinetics. As the chain length of the glucosides increased, the uptake continued to diminish to octyl glucoside, increased at decyl glucoside, and then diminished progressively thereafter. Phlorizin totally inhibited the uptake of glucosides with chain lengths from 1 to 8 carbon atoms in the aglycone. With increased aglycone chain length, phlorizin inhibition dropped to the range 40-50% for the decyl, dodecyl, and tetradecyl glucosides. In the absence of Na$^+$, there was almost no uptake for glucosides with chain lengths 1-8. There was a 30-40% reduction of uptake with increased alkyl chain length. The results show that glucosides with a long alkyl chain (2-18 carbon atoms) as the aglycone can be transported by carrier-mediated processes in the hamster small intestine *in vitro.*

6933 EFFECT OF NON-IONIC DETERGENTS ON THE ABSORPTION OF FAT AND α-TOCOPHEROL IN THE RAT.

(Eng.) Sheltawy, M. J.; Losowsky, M. S. (St. Jame's Hosp., Leeds, LS9 7TF, England). *Nutr. Metab.* 18(5/6):265-271; 1975.

Because an earlier study suggested that polyoxyethylene sorbitan monoleate (PSM) reduced the binding capacity of cholestyramine for bile salts, fecal bile salt levels were measured in male Wistar rats fed a 5% cholestyramine diet alone or in combination with 2% PSM or 2% polyoxypropylene polyoxyethylene polymer (PPP) for 7 days. The fat absorption, the absorption rates of radioactive α-tocopherol (1 μCi), and the serum cholesterol levels were also measured in the rats on the different diets. Fecal bile salt levels were significantly increased by including cholestyramine in the diet, from a mean control level of 4.6 mg/day to 21.3 mg/day. This effect was not significantly diminished by including either of the detergents in the diet. The mean level of fat absorption on the control diet (94%) was significantly reduced (55.8%) when cholestyramine was added to the diet. The addition of PSM to this diet did not significantly increase fat absorption, but the addition of PPP markedly increased absorption to 75.4% ($p<0.001$). The mean level of α-tocopherol absorption on the control diet (58.8%) was significantly reduced (21%) when cholestyramine was added, and this was not significantly changed by either detergent. The proportion of radioactivity remaining in the liver 5 days after the administration of radioactive α-tocopherol was increased when PSM or PPP was present, perhaps indicating increased absorption via the portal vein. The results suggest that PPP may be of therapeutic value in aiding fat absorption where bile salts are deficient.

6934 EVIDENCE FOR THE SECRETORY TRANSPORT MECHANISM OF INTESTINAL IMMUNOGLOBULIN. THE ULTRASTRUCTURAL DISTRIBUTION OF IgM.

(Eng.) Allen, W. D.; Smith, C. G.; Porter, P. (Unilever Research Lab., Colworth House, Sharnbrook, Bedford, England). *Immunology* 30(3):449-457; 1976.

The intracellular localization of immunoglobulin M (IgM) in porcine intestinal tissue was studied by immunoelectron microscopy and immunofluorescence. Tissues from the proximal duodenum, mid-jejunum, and terminal ileum were stained with fluorescein isothiocyanate (FITC)-labeled antisera. There were three distinct zones of staining. Numerous lymphoid cells with bright cytoplasmic staining were seen in the intercryptal lamina propria. Intense staining was also seen in the apical cytoplasm of crypt epithelial cells, mainly the supranuclear region. The third zone was in the lumen of blood vessels, particularly the subepithelial capillary loops. Although there were fewer IgM-containing vesicles in the crypt epithelium than those containing IgA (seen previously), their location within the cytoplasm was similar. These observations indicate a degree of selective transport. Although crypt epithelial cells can transport both Ig simultaneously, factors other than competition by secretory Ig for common receptor sites may be involved.

6935 EFFECTS OF ALCOHOL ON ION TRANSPORT BY ISOLATED GASTRIC AND ESOPHAGEAL MUCOSA.

(Eng.) Fromm, D.; Robertson, R. (Beth Israel Hosp., 330 Brookline Ave., Boston, MA 02215). *Gastroenterology* 70(2):220-225; 1976.

The effects of 20% ethyl alcohol on steady state rates of ion transport were studied in isolated rabbit gastric and esophageal mucosa. The initial mean rate of acid secretion in the fundic mucosa was 2.6 μEq/hr/cm^2. The luminal, but not serosal, addition of alcohol decreased this rate by 1.8 μEq/hr/cm^2 (p<0.001). This change was associated with a decrease in the mean potential difference (PD), from 3.3 mV to 0.4 mV (p<0.01) and mean electrical resistance, from 109 ohms/cm^2 to 54.5 ohms/cm^2 (p<0.001). The rate of alcohol secretion in the presence of alcohol in the lumen was resistant to stimulation by serosal addition of 0.09 mM histamine, 10 mM theophylline, 2 mM dibutyryl cyclic AMP, and porcine gastrin (0.5 μg/ml). In antral mucosa, the mean rate of luminal acid loss (0.7 μEq/hr/cm^2) was increased by 0.7 μEq/hr/cm^2 (p<0.001) after the addition of alcohol. In the absence of alcohol, there was a net secretion of Na and Cl across the antral mucosa. When alcohol was added, the net Na flux was not significantly different from zero (p>0.5), and a 63% reduction (p<0.001) in net Cl secretion occurred. These changes were associated with significant increases in the unidirectional luminal to serosal and serosal to luminal fluxes of Na and Cl and with a significant decrease in electrical resistance. The mean rate of luminal acid loss in the presence of 0.001 mM ouabain (0.8 μEq/hr/cm^2) increased by 1.0 μEq/hr/cm^2 (p<0.001) following the addition of alcohol, and the electrical resistance decreased significantly by 89.7 ohms/cm^2. Alcohol had no effect on the rate of luminal acid loss or electrical resistance of esophageal mucosa. The luminal application of alcohol inhibits active ion transport, in addition to increasing cation and anion permeability. Inhibition of active transport *per se* is not necessarily associated with an increase in mucosal permeability.

6936 INFLUENCE OF REPRODUCTIVE STATE ON INTESTINAL FLUID AND ION TRANSPORT BY THE RAT JEJUNUM, IN RELATION TO THE POSSIBLE CONTRIBUTION OF PROLACTIN.

(Eng.) Mainoya, J. R. (Dept. Zoology, Univ. Dar-es-Salaam, Dar-es-Salaam, Tanzania). *J. Endocrinol.* 67(3):351-358; 1975.

The ability of everted jejunal sacs (segments III and IV) to transport fluid and electrolytes was determined in Sprague-Dawley rats at various stages of the estrus cycle and of pregnancy. The mean levels of fluid and NaCl absorption in both jejunal segments were significantly higher during pro-estrus (1.48 ml/g/hr, 223.8 μEq/g/hr, and 35.4 μEq/g/hr for mucosal fluid, Na$^+$, and Cl$^-$ transport, resp., in jejunal segment III; 1.59 ml/g/hr, 224.9 μEq/g/hr, and 26.7 μEq/g/hr, resp., in segment IV) and in estrus (1.57 ml/g/hr, 200.2 μEq/g/hr, and 30.1 μEq/g/hr, resp., in segment III; 1.85 ml/g/hr, 240.9 μEq/g/hr, and 29.2 μEq/g/hr, resp. in segment IV) than in diestrus (0.96 ml/g/hr, 122.1 μEq/g/hr, and 10.3 μEq/g/hr, resp., in segment III; 1.12 ml/g/hr, 143.7 μEq/g/hr, and 6.6 μEq/g/hr, resp., in segment IV). The s.c. administration of prolactin (1.0 mg, 48 and 24 hr before sacrifice) significantly increased mucosal fluid and ion transfer in diestrus rats (1.57 ml/g/hr, 227.3 μEq/g/hr, and 63.3 μEq/g/hr, resp., in segment III; 1.79 ml/g/hr, 245.5 μEq/g/hr, and 61.4 μEq/g/hr, resp., in segment IV) in comparison with untreated diestrus rats (0.73 ml/g/hr, 105.3 μEq/g/hr, and 8.6 μEq/g/hr, resp., in segment III; 0.97 ml/g/hr, 124.6 μEq/g/hr, and 11.5 μEq/g/hr, resp., in segment IV), but not in estrus rats. Ovariectomy in diestrus rats had no significant effect on fluid and sodium absorption, but resulted in increased chloride absorption in segment III. Treatment with s.c. estradiol benzoate (5 μg/day, 4 days) caused increases in mucosal fluid and sodium, but not chloride transport in ovariectomized diestrus rats (1.36 ml/g/hr and 170 μEq/g/hr, resp., in segment III; 1.65 ml/g/hr and 188.4 μEq/g/hr, resp., in segment IV) in comparison with untreated ovariectomized animals (1.04 ml/g/hr and 129.1 μEq/g/hr, resp., in segment III; 1.18 ml/g/hr and 136.4 μEq/g/hr, resp., in segment IV). Progesterone treatment (1.0 mg/day, 4 days, s.c.) had no influence on fluid and sodium transport, but inhibited chloride absorption. The intestinal absorption of fluid, sodium, chloride, potassium, calcium, and magnesium was significantly increased in midpregnant and lactating rats. When these animals were treated with 2-Br-α-ergocryptine (60 μg/day, 5 days, s.c.), the absorption rates were depressed, although they were still higher than those in diestrus rats. Lactating rats suckling up to the time of the experiment had significantly increased mucosal fluid and NaCl transfer. Lactating rats, not suckled for 24 hr or subjected to a reduction in the number of pups from eight to three, did not show major changes in intestinal fluid or NaCl absorption. The data suggest that increases in intestinal transport during estrus, pregnancy, and lactation are attributable to hormonal changes to which prolactin may make an important contribution.

6937 A MODEL SYSTEM FOR INVESTIGATING THE BILIARY EXCRETION OF AN ANION IN THE RAT.

(Eng.) Powell, G. M.; Jones, J. G.; Olavessen, H. A.; Curtin, C. G. (Dept. Biochemistry, Univ. Coll., P.O. Box 78, Cardiff CF1 1XL, U.K.). *Biochem. J.* 148(2):303-307; 1975.

The validity of a model system for investigating the biliary excretion of phenolphthalein di[^{35}S]sulfate, specifically, the mechanisms by which this conjugate is transferred into bile, was studied. The conjugate was administered to male MRC hooded rats with bile duct fistulas by continuous i.v. infusion at 3, 4.5, 6, 9, and 12 μg/min or in single doses of 1.4-16 mg. The excretion rate of the ester into bile increased with time, eventually reaching steady state. Each steady-state value was considerably less than its corresponding infusion rate (five dose mean 68% ± 16%). The lag period before the steady-state showed no correlation with infusion rate (mean lag 22.2 ± 5.9 min). There was no positive correlation between bile production and infusion rate, but there was a correlation between bile production and the proportion of conjugate excreted in the bile. The results of the single-dose experiments were similar, illustrating that the model may also be applied to single-dose studies. An essential feature of this model is the presence of a compartment into which the ester may pass as an alternative to direct excretion via the bile. Whole-body radioautography experiments, in which each animal received 1 mg conjugate/0.2 ml water i.v., were performed to locate this compartment. Since there was a significant accumulation of radioactivity in the liver only, this compartment may be located in the liver.

6938 EFFECTS OF CALCIUM SOLUBILITY ON ABSORPTION BY RATS WITH INDUCED ACHLORHYDRIA.

(Eng.) Mahoney, A. W.; Holbrook, R. S.; Hendricks, D. G. (UMC 87, Utah State Univ., Logan, UT 84322). *Nutr. Metab.* 18(5/6):310-317; 1975.

Calcium absorption was studied in achlorhydric male Sprague-Dawley rats. The rats were made achlorhydric by x-irradiating the stomach, and sham-operated animals served as controls. The rats were fed diets containing very soluble calcium chloride or calcium gluconate, or slightly soluble calcium carbonate or tricalcium phosphate for 3 weeks. X-irradiated rats fed the diet containing calcium chloride had greater bone strength (5.00 kg) than the x-irradiated rats fed calcium carbonate (3.97 kg). However, the x-irradiated achlorhydric rats were unable to deposit as much calcium in their femurs as sham-operated controls fed the same diet (186 g/kg intake versus 264 g/kg, $p<0.05$). The x-irradiated rats fed diets containing tricalcium phosphate or calcium gluconate had consistently higher mean gastric pH values (6.8 and 7.0, resp.) and absorbed less calcium (-70 and 254 g/kg intake, resp.) than did the sham-operated controls [gastric pH 3.7 and 1.8 on $Ca_3(PO_1)_2$ or Ca gluconate diets, resp.; absorption 404 and 345 g/kg, resp.]. The x-irradiated rats fed slightly soluble tricalcium phosphate had much smaller (1.63 g/kg) and weaker (3.64 kg) femurs that contained less calcium and phosphorus (134 and 79 g/kg air-dry bone) than did controls fed the same diet (1.85 g/kg, 8.32 kg, 209 g/kg, and 85 g/kg, resp.) or x-irradiated animals fed Ca gluconate (2.24 g/kg, 6.69 kg, 213 g/kg, and 90 g/kg, resp.). Apparently, the very soluble dietary calcium offset the impaired calcium absorption of achlorhydric rats.

6939 MECHANISMS OF THE ABSORPTION OF WATER-SOLUBLE DYES FROM THE RAT SMALL INTESTINE.

(Eng.) Nakamura, J.; Yoshizaki, Y.; Yasuhara, M.; Kimura, T.; Muranishi, S.; Sezaki, H. (Faculty Pharmaceutical Sciences, Kyoto Univ., Yoshida Shimoadachi-cho, Sakyo-ku, Kyoto, Japan). *Chem. Pharm. Bull. (Tokyo)* 24(4):683-690; 1976.

The absorption of four water-soluble dyes, methylene blue (MB), bromthymol blue (BTB), bromphenol blue (BPB), and phenol red (PR), from the small intestine of male Wistar albino rats was investigated. An *in situ* perfusion technique was used in which 40 ml of dye solution were recirculated through the intestine at a rate of 5 ml/min. Homogenates were prepared from the isolated small intestine, and the amount of dye was determined spectrophotometrically. The net absorption of MB, BTB, BPB, and PR was 46.0%, 14.7%, 2.4%, and 1.2%, resp. The degree of binding to mucosal homogenates, determined *in vitro*, was correlated to the percentage disappearance from the lumen and tissue accumulation rather than net absorption. Binding to brush borders was related to the degree of uptake by the isolated epithelial cells. These results suggest that binding to the mucosa, especially to the brush borders (microvilli) as the first step, is important in the absorption of these water-soluble dyes from the rat small intestine. The poor absorbability of PR is due to its low affinity to the intestinal mucosa and its poor lipoid solubility.

6940 INHIBITION OF WATER ABSORPTION IN THE INTESTINE BY Staphylococcus aureus DELTA-TOXIN.

(Eng.) Kapral, F. A.; O'Brien, A. D.; Ruff, P. D.; Drugan, W. J., Jr. (Dept. Medical Microbiology, Ohio State Univ., Columbus, OH 43210). *Infect. Immun.* 13(1):140-145; 1976.

To determine whether *Staphylococcus aureus* delta toxin affects water absorption in the intestine, water absorption was monitored by measuring the concentration of polyethylene glycol in a solution continuously perfused through the lumen of jejunal and ileal segments of the rabbit *in vivo* and of ileal segments of the guinea pig *in vitro*. In the proximal rabbit jejunum, water absorption was reduced by 1 mg/ml of delta toxin and completely inhibited by 2 mg/ml of toxin. With the larger dose, movement of fluid into the lumen occurred after 3 hr. In the distal jejunum, the lower dose increased water absorption, but the higher dose reduced absorption for 4 hr. Both doses produced a consistent response in the ileum. At 2 mg/ml, there was an immediate cessation of water absorption, which persisted throughout the 6-hr experimental period. Guinea pig ileal segments *in vitro* demonstrated a net transfer of water from mucosa to serosa that was inhibited by both doses of toxin. The dose required to cause inhibition of water absorption in 50% of the guinea pig ileal segments was calculated to be 300 μg/ml. Cholera toxin (0.5 μg/cm^2 of mucosa) inhibited water absorption *in vitro*, but *S. aureus* enterotoxin B (5 μg/cm^2) had no effect. The results show that delta toxin interferes with intestinal water absorption *in vivo* and *in vitro*.

Since water movement across the mucosa is secondary to ion transport, these findings suggest that the primary action of delta toxin is alteration of normal ion transport.

6941 POLYCHLORINATED BIPHENYLS AND INTESTINAL ABSORPTION OF D-GLUCOSE IN MICE. (Eng.)

MOTILITY

6943 EFFECTS OF PGA AND PGB COMPOUNDS ON GASTROINTESTINAL TRACT SMOOTH MUSCLE FROM MAN AND LABORATORY ANIMALS. (Eng.)

Adaikan, P. G.; Karim, S. M. M. (Kandang Kerbau Hosp., Univ. Singapore, Singapore 8). *Prostaglandins* 11(1):15-22; 1976.

The effects of prostaglandin E_2 (PGE_2), $PGF_{2}\alpha$, PGA_1, PGA_2, PGB_1, and PGB_2 on the longitudinal and circular muscle from the body of human stomach were studied, and their relative potencies on the longitudinal muscles of the gastrointestinal tract from rat, hamster, guinea pig, and chicken were investigated. The prostaglandins contracted longitudinal muscle of the human stomach. The potencies in decreasing order, together with the threshold dose range, were: PGE_2 (4-80 ng/ml), PGB_2 (10-400 ng/ml), $PGF_{2}\alpha$ (25-800 ng/ml), PGA_2 (160-400 ng/ml), PGB_1 (16-800 ng/ml), and PGA_1 (200-400 ng/ml). In the circular muscle of the human stomach, the most potent stimulant was PGB_2 (40-400 ng/ml), followed by $PGF_{2}\alpha$ (40-800 mg/ml), PGA_2 (100-1,600 ng/ml), PGB_1 (200-800 ng/ml), and PGA_1 (800-4,000 ng/ml). PGE_2 had a relaxant effect on all circular muscle strips, the threshold dose being within the range 0.1 and 0.4 μg/ml. In four circular muscle strips, the tone of the muscle did not return to the basal level after contractions were induced with either PGA_2 or PGB_2. In these strips, small doses of $PGF_{2}\alpha$ (100-200 ng/ml) produced contraction, followed by marked relaxation of the muscle. In circular strips not previously exposed to PGA_2 or PGB_2, increasing the applied load of PGF_{2_α} from the usual 1.5 g (which produced contraction) to 3.5 g also resulted in relaxation. This effect was not seen with longitudinal muscle strips. PGA_1, PGA_2, PGB_1, and PGB_2 showed weak smooth muscle-stimulating activities compared to PGE_2 and $PGF_{2}\alpha$. The results show that PGA and PGB compounds are not inactive derivatives of E prostaglandins, but have potent smooth muscle-stimulating activities.

6944 EFFECT OF SECRETIN, GLUCAGON AND VIP ON GALLBLADDER CONTRACTION. (Eng.)

Vagne, M.; Troitskaja, V. (Unite de Recherches de Physiopathologie digestive, Inserm U-45, Hopital Edouard-Herriot, Pavillon Hbis, F-69374 Lyon Cedex 2, France). *Digestion* 14(1):62-67; 1976.

Because of the structural similarities of the peptides, secretin, glucagon, and vasoactive intestinal peptide (VIP), their effects on cholecystokinin (CCK, 0.05, 0.1, 0.2, and 0.4 U, i.v.)-induced gallbladder contraction were studied *in vivo* in the guinea pig. The gastric secretions in each animal were diverted, and gallbladder contraction was measured using a length transducer and recorder. Secretin (1, 4, and 16 U), glucagon (1, 4, and 16 μg), and VIP (0.05, 1, and 2 μg) were administered i.v. 1 min before the CCK injection. Secretin caused a significant increase in the amplitude and duration of CCK responses. Given with each of the three doses of CCK, 16 U of secretin produced the same response as doubling the CCK dose. Glucagon increased the responses slightly. VIP decreased the responses to all doses of CCK. The calculated mean showed a decrease to about half of CCK response alone. The results show that three structurally related peptides of the gastrointestinal tract have different effects on gallbladder contraction.

6945 EFFECT OF AN ELEMENTAL DIET ON THE ELECTRICAL ACTIVITY OF THE SMALL INTESTINE IN DOGS. (Eng.)

Moore, E. P.; Copeland, E. M.; Dudrick, S. J.; Weisbrodt, N. W. (John Peter Smith Hosp., Ft. Worth, TX). *J. Surg. Res.* 20(6):533-537; 1976.

Because it has been postulated that elemental diets rest the small bowel by decreasing motility and secretions, the effects of an elemental diet on the patterns of motility of the small intestine were investigated in three dogs. Fourteen silver electrodes were fixed equidistant along the serosal surface of the entire small intestine. Recordings (1-4 hr) were made in conscious animals that were fed for several weeks on a normal dog food diet, both after an 18-hr fast and immediately following the ingestion of 1 lb of dog food. Similarly, records were obtained after fasting and after feeding the elemental diet. In all recordings obtained during fasting, cyclically recurring myoelectric complexes were evident; the overall average number of slow waves with spike potentials at one electrode during 1 hr of recording was 196. Feeding dog food elicited a pattern characterized by a more continuous level of spike potentials at all electrode sites; at no time did the level of activity approach 100%, and seldom did it fall to zero. The average number of slow waves with spike potentials at one electrode in the three dogs was 499. The ingestion of an elemental diet elicited a pattern that was more uniform than that seen during fasting, and the number of slow waves with spike potentials was significantly less than that measured following a meal of canned dog food. Fewer spike potentials occurred in the distal small intestine; consequently, the average number of slow waves with spike potentials at one electrode in the proximal bowel was 304. The results suggest that although i.v. hyperalimentation is the best way of obtaining optimal bowel rest, the ingestion of a chemically defined diet is significantly better than ingestion of a regular diet.

6946 THE DEPRESSOR EFFECT OF DOPAMINE ON THE ELECTRICAL AND MECHANICAL ACTIVITIES OF CAT SMALL INTESTINE. (Eng.) Ohkawa, H.; Watanabe, M. (Dept. Physiology, Yamaguchi Univ. Sch. Medicine, Ube, Japan). *Tohoku J. Exp. Med.* (1):69-77; 1975.

The inhibitory actions of externally applied dopamine and other adrenergic stimulants on the electrical and mechanical activities of the adult cat small intestine were observed using pressure electrodes. D,L-(3,4-dihydroxyphenyl)analine (DOPA, 10^{-7}-10^{-5} g/ml) and dopamine (10^{-6}-10^{-5} g/ml) reduced the spike and mechanical activities. The effects of dopamine were suppressed by treatment with phentolamine (10^{-5} g/ml), phenoxybenzamine (10^{-6} g/ml), or propranolol (10^{-5} g/ml). This showed that the β-response was predominant in the intestine. Noradrenalin (10^{-6} -10^{-5} g/ml) and adrenalin (10^{-6} g/ml) also blocked spike generation and depressed mechanical activity; however, these actions in turn were abolished by adrenergic blockers (dibenamine, 10^{-5} g/ml, and propranolol, 10^{-5} g/ml). No significant effects of normetanephrine and metanephrine were detected. Dose-response curves for acetylcholine with and without dopamine, isoproterenol, phenylephrine, and noradrenalin were obtained. Those with the adrenergic stimulants were shifted to higher concentrations of acetylcholine. It is concluded that dopamine acts on α- and β-receptors, and there is no direct evidence for the presence of separate dopamine receptors.

6947 EFFECT OF PROSTAGLANDIN $F_{2}\alpha$ ON PROPULSIVE ACTIVITY OF THE ISOLATED SEGMENTAL COLON OF THE GUINEA-PIG. (Eng.) Ishizawa, M.; Miyazaki, E. (Sapporo Medical Coll., W. 17, S.1, Sapporo, Japan). *Prostaglandins* 10(5):759-768; 1975.

The effects of prostaglandin $F_{2}\alpha$ ($PGF_{2}\alpha$) on propulsive activity were investigated *in vitro* in 3-cm distal colon segments and colonic longitudinal and circular muscle strips from guinea pigs. $PGF_{2}\alpha$ (5×10^{-8}-1×10^{-6} M), added to the bathing medium, increased propulsive activity in a concentration-dependent manner. This increase was abolished in the presence of atropine or tetrodotoxin (1×10^{-7} g/ml). The contractions produced by $PGE_{2}\alpha$ (5×10^{-7}-1×10^{-5}M) in isolated longitudinal and circular smooth muscle strips were unaffected by atropine or tetrodotoxin (1×10^{-7}g/ml). It is concluded that propulsive activity stimulated by $PGF_{2}\alpha$ may depend on the contractions of both muscle layers and stimulation of the peristaltic reflex.

6948 MOTILITY OF THE LARGE INTESTINE OF PIEBALD-LETHAL MICE. (Eng.) Brann, L.; Wood, J. D. (Univ. Kansas Medical Center, Kansas City, KS 66103). *Am. J. Dig. Dis.* 21(8):633-640; 1976.

To determine whether the contractile activity of the musculature of the large intestine of piebald-lethal mice is abnormal only in the terminal segment, which is hypoganglionic, the *in vitro* propulsion of artificial fecal pellets was observed in the colons of these animals and in the colons of normal siblings. Peristaltic activity in the isolated large intestines of normal mice propelled the artificial fecal pellets from the proximal colon to the anal end of the intestine. Peristalsis was blocked by the administration of lidocaine HCl (1×10^{-5} g/ml), which resulted in a 10-15% increase in bowel length. These observations indicate that contractile activity of the external muscularis during peristalsis is coordinated by intrinsic neuronal mechanisms and that coordinated propulsion of a solid bolus can occur in the absence of extrinsic autonomic innervation. In most of the preparations from the piebald mice, the colon was distended by impacted fecal matter. The rectal region was constricted and contained no fecal matter. When the lumen was cleared of fecal content, artificial fecal pellets were actively propelled throughout the previously distended region of the colon, but propulsion did not continue beyond the proximal margin of the terminal aganglionic segment. This indicates that the peristaltic mechanisms for propulsion of an intraluminal bolus are functional in the dilated portion of the colon and nonfunctional in the terminal segment. In 19 of 22 preparations, the pellet stopped at the terminal segment and was then actively propelled in the reverse direction back through the dilated portion of the colon. Reverse peristalsis was also seen in colon preparations of rats with imperforate anus and in preparations of normal intestine obstructed with a ligature, suggesting that reverse peristalsis may be a general response to distal obstruction, and implying that the distended portion of the colon of piebald mice is capable of coordinated peristalsis.

6949 GASTRIC PACEMAKERS. (Eng.) Sarna, S. K.; Bowes, K. L.; Daniel, E. E. (McMaster Univ. Medical Center, 1200 Main St. West, Hamilton, Ontario, Canada L8S 4J9). *Gastroenterology* 70(2): 226-231; 1976.

Experiments were carried out to determine if a reversal in the direction of phase lag among control waves by an electronic pacemaker surgically implanted near the pylorus in dogs would reverse the sequence of normal aborad contractions and delay gastric emptying. Electrical stimulation was applied to 5.8-6.0 pulses/min, 50-80 msec pulse width, and 10-14-volt pulse amplitude. When liquid gastric emptying was measured by introducing 400-600 ml of phenol red by a nasogastric tube through an esophagostomy into the stomach and by withdrawing the remainder after 5- and 15-min periods, the mean percentage of phenol red remaining in the stomach with the pacemaker on was 51.2% and with the pacemaker off, 24.2%. The sequence of the occurrence of electrical response activity was reversed, indicating that the contractions originated near the pylorus and moved orally. When liquid gastric emptying was measured by the above method, but with barium sulfate mixed with phenol red (10 g/100 ml phenol red), the mean percentage volume of meal remaining in the stomach after 15 min with the pacemaker was 49.1%, and without the pacemaker, 25.2%. With this meal, the sequence of contractions observed on an image intensifier was orad with the pacemaker and aborad without the pacemaker. Solid meal emptying was measured using radiological image intensifier observation of the gastric emptying of small barium-filled balls. When the pacemaker was turned off, the emptying patterns of the spheres was unpredictable, the emptying time varying from 15 to 150 min. With the pacemaker on, the spheres were pushed back into the proximal stomach, due to orad sequential contractions. In one experiment, all 15 spheres normally emptied in 135 min; with the pacemaker on, none of the spheres emptied at the end of 300 min. These studies show that sequential aborad contractions in the stomach play an important role in the emptying of liquid and solid meals.

6950 THE ROLE OF ADRENERGIC RECEPTORS IN THE REGULATION OF GASTRIC MOTILITY IN THE RAT. (Eng.) Gati, T.; Gelencser, F.; Hideg, J. (Semmelweis Medical Univ., Budapest 9, Hungary). *Z. Exp. Chir.* 8(3):179-184; 1975.

Experiments were carried out in rats to determine whether the inhibitory effect of epinephrine and norepinephrine on gastrointestinal motility is mediated through alpha or beta adrenergic receptors. When the animals received 2.5 μg/100 g of epinephrine or norepinephrine 30 min before and seven times every 30 min after the intragastric administration of radiopaque material, most of the opaque material remained in the stomach after 3 hr; in controls, the radiopaque material had fully evacuated by this time. Pylorotomy did not affect epinephrine-induced inhibition of gastric motility. Gastric evacuation was unaffected 3 hr after the i.p. administration of phenylephrine (0.5 mg/100 g), the mean evacuation after 3 hr being 89%. When the same amounts of phenoxybenzamine, isoproterenol, and propranolol were administered i.p., the mean evacuation was 63%, 25%, and 95%, resp. Pretreatment with phenoxybenzamine (an alpha receptor blocking agent) had no effect on epinephrine-induced inhibition of gastric motility; the mean evacuation 3 hr after the administration of both drugs was 30%. Pretreatment with propranolol (a beta receptor blocking agent) completely blocked the effect of epinephrine, a mean evacuation of 88%. The results suggest that epinephrine exerts its inhibitory effect on gastric motility via adrenergic beta receptors.

6951 INFLUENCE OF THE REMOVAL OF EXTERNAL Na ON THE TONUS AND DRUG-INDUCED CONTRACTION OF THE ISOLATED RAT RECTUM, PARTICULARLY IN RELATION TO Ca. (Eng.) Taniyama, K.; Araki, H.; Cheng, J. T.; Maeda, M.; Matsumoto, H. (Kobe Univ. Sch. Medicine, Kobe, Japan). *Kobe J. Med. Sci.* 21(4):97-108; 1975.

6952 EFFECTS OF AMINOPHYLLINE AND THE REMOVAL OF EXTERNAL Na ON THE ANTISPASMODIC ACTION OF ISOPROTERENOL IN ISOLATED RAT RECTUM, PARTICULARLY IN RELATION TO Ca. (Eng.) Taniyama, K.; Takahashi, N.; Cheng, J. T.; Kosuda, T.; Matsumoto, H. (Kobe Univ. Sch. Medicine, Kobe, Japan). *Kobe J. Med. Sci.* 21(4):109-115; 1975.

6953 ON THE MECHANISM OF THE RELAXING ADRENALINE EFFECT ON CAT JEJUNUM. (Eng.) Petkov, V.; Radomirov, R. (Inst. Physiology, Bulgarian Acad. Sciences, Bulgaria). *Acta Physiol. Pharmacol. Bulg.* 3/4:41-50; 1976.

SECRETION AND METABOLISM

6954 SUPPRESSION OF GASTRIN RELEASE AND GASTRIC SECRETION BY GASTRIC INHIBITORY POLYPEPTIDE (GIP) AND VASOACTIVE INTESTINAL POLYPEPTIDE (VIP). (Eng.) Villar, H. V.; Fender, H. R.; Rayford, P. L.; Bloom, S. R.; Ramus, N. I.; Thompson, J. C. (Univ. Texas Medical Branch, Galveston, TX 77550). *Ann. Surg.* 184(1):97-102; 1976.

The effects of gastric inhibitory polypeptide (GIP) and vasoactive intestinal peptide (VIP) on basal and food-stimulated serum gastrin and gastric acid secretion levels were studied in five Heidenhain pouch dogs. On random days during a 7-day test period, either normal saline or GIP (2 μg/kg/hr) or VIP (1 μg/kg/hr) was infused for 1 hr, after which each dog was given a high protein meal. Neither GIP nor VIP infusions had an effect on basal gastrin levels. When the dogs were fed and the infusions continued, the mean serum gastrin levels in the controls, GIP-infused, and VIP-infused dogs increased from baseline levels of 46-59 pg/ml to peak levels of 517, 409, and 298 pg/ml, resp.; these levels were achieved at 15, 15, and 90 min, resp. In controls, the gastrin level remained at a plateau above 450 pg/ml throughout the study, while it progressively declined in the sera of dogs infused with GIP and VIP. The serum gastrin concentrations in the dogs receiving GIP were significantly lower than those in controls at 120 and 180 min, and the values in dogs receiving VIP were significantly lower at 65, 120, 150, and 180 min. At 90 min, the control gastrin concentration of 494 pg/ml was diminished by approximately 30% by GIP and by 40% by VIP. The relative molar concentration of GIP to VIP was 19:1. These results suggest that VIP is a much more potent inhibitor of gastrin release than is GIP. The gastric acid output in the controls was approximately 50% more than in dogs that received GIP or VIP, but this suppression was not statistically different. The mean basal insulin levels were 13.9, 15.5, and 16.7 μU/ml in the control, GIP, and VIP groups, resp. GIP caused a significant insulin elevation at 30 min (19.1 μU/ml), and food plus GIP caused significant insulin elevations at 90 min (22.1 μU/ml) and 120 min (24.8 μU/ml). The insulin levels were significantly increased above basal levels at 90 min (37.5 μU/ml), 150 min (21.4 μU/ml), and 180 min (21.4 μU/ml) after VIP infusion. Since there was no associated release of glucose with the increase in insulin levels with GIP, it may be assumed that GIP is insulinotropic. Measurements of GIP and VIP by specific radioimmunoassays showed that VIP infusion had no effect on GIP plasma levels and *vice versa*. GIP plasma levels increased during GIP infusion, and VIP plasma levels increased during VIP infusion, indicating that these polypeptides are immunologically recognizable in circulation.

SECRETION AND METABOLISM

Stomach

6956 THE EFFECTS OF ATROPINE ON THE RESPONSE TO PENTAGASTRIN OF ANAESTHETISED AND CONSCIOUS DOG PREPARATIONS. (Eng.) Schofield, B.; Tepperman, B. L.; Davison, J. S. (Div. Medical Physiology, Univ. Calgary, 2920 24 Ave. N.W., Calgary, Alberta, Canada T2N IN4). *Rend. Gastroenterol.* 7 (3):147-152; 1975.

The effect of the i.v. administration of atropine on gastrin-stimulated acid secretion was studied in anesthetized and conscious dogs with intact stomachs or Heidenhain pouches, some of which had gastric fistulae. Atropine (100 μg/kg) produced no significant change in pentagastrin (0.05 μg/kg/min, i.v.)-stimulated acid secretion in whole stomachs of dogs anesthetized with 2% α-chloralose (80 mg/kg, i.v.). When atropine (25 μg/kg) was administered 45 min prior to the administration of anesthesia in Heidenhain pouch dogs, the pentagastrin-stimulated acid secretion was inhibited to 51% of the initial level. In dogs with a gastric fistula, atropine also produced a significant reduction (-59%) of pentagastrin-stimulated secretion. In further experiments, atropine (25 μg/kg) was administered to conscious animals during peak Heidenhain pouch secretion induced with pentagastrin (0.16 μg/kg/min). There was an inhibition (-48%) of the same order as that seen in the anesthetized animals. It appears that pentagastrin-stimulated acid secretion is not affected by the administration of anesthesia.

6957 THE DEVELOPMENT OF A RELIABLE AND SENSITIVE BIOASSAY FOR GASTRIN IN BODY FLUIDS. (Eng.) Halter, F.; Kohler, B.; Leuenberger, J.; Smith, G. M.; Varga, L. (University Hosp., Inselspital, Berne, Switzerland). *Eur. J. Pharmacol.* 35 (2):369-378; 1976.

The sensitivity and reliability of the Ghosh and Schild rat stomach preparation to gastrin were improved to facilitate the preoperative diagnosis of the Zollinger-Ellison syndrome and to correlate the gastrin bio- and immunoassays on a large scale. A bulky intragastric cannula was implanted in male Wistar rats; the perfusate was recirculated, and conductivity was measured instead of pH. With these procedures, the threshold values for synthetic human gastrin I (HG I) were in the range of 1-2 ng. Neither vagotomy nor antrectomy influenced the sensitivity of the method. The threshold values were not lowered by attempts to reduce gastrin metabolism through nephroligature or small bowel resection. Although portacaval shunts did raise the threshold, the limited increase in sensitivity was also achieved by selecting rats that gave an initially high response to a test dose of gastrin, avoiding the complicated shunt operation. The assay procedure enabled statistically valid measurements of gastrin in plasma and in tumor extracts from patients suffering from the Zollinger-Ellison syndrome to be assayed using a 2 + 2 block design. In comparison to earlier re-perfusion systems, this method is not only simpler and more precise, but considerably more sensitive.

6958 IMMUNOREACTIVE GASTRIN IN DIFFERENTIAL AND DENSITY GRADIENT FRACTIONS OF RAT GASTRIC MUCOSA. (Eng.) Trotman, C. N. A.; Fiddes, I. J. S.; Grund, E. R.; McHanwell, S.; Sanders, D. J.; Sanderson, C.; Shaw, B. (Dept. Physiology, Medical Sch., Univ. Newcastle upon Tyne, Newcastle upon Tyne, NE1 7RU, England). *J. Endocrinol.* 68(1):5-12; 1976.

Gastrin storage granules or vesicles were separated from the nuclei and mitochondria of Wistar rats to facilitate studies of the functional properties of the vesicle membrane and the molecular composition of the vesicle contents. The distribution of immunoreactive gastrin and the subcellular markers between four particulate fractions and the supernatant from rat gastric mucosal homogenates were determined, and the gastrin storage vesicles were further characterized by isopycnic equilibration in continuous sucrose density gradients. The distribution of marker enzymes confirmed that a 10% (weight/volume) homogenate of rat gastric mucosa could be fractionated without very serious interference from mucus. The mucosa was homogenized and centrifuged before and after its direct application to the gradient. The sedimentational properties of subcellular gastrin-containing structures were distinct from those of the mitochondria. After centrifugation, the peak of immunoreactive gastrin was found in sucrose with a density of 1.17 to 1.18 g cm^{-3} (1.35 M, 39.5%, weight/weight), and the individual peaks were consistently close to this value. This finding was independent of the magnitude of the peak, which varied widely between 3.4 and 125 ng of immunoreactive gastrin, except that smaller peaks were sharper. A thermolabile component with ^{125}I-labeled gastrin-binding activity present in gastric mucosal homogenates and fractions was not associated with the gastrin storage vesicles sedimenting in density gradients. The possibilities that the binding activity is intravesicular and that it may be concerned with gastrin storage are unlikely.

6959 RESPONSE OF SECRETING AND NONSECRETING GASTRIC MUCOSA TO H^+ BACK-DIFFUSION. (Eng.) O'Brien, P.; Fromm, D.; Silen, W. (Harvard Medical Sch., Boston, MA). *Surg. Forum* 26:378-380; 1975.

The influence of the secretory state of the bullfrog gastric mucosa on the ability of this tissue to withstand back-diffusion of H^+ was studied by passing an electric current through the tissue; the consequences of the current in spontaneously secreting and inhibited mucosae were also studied. Thirty minutes after the induction of H^+ back-diffusion in nonsecreting mucosa by the passage of current (510 μa/cm^2), an 87% reduction in the potential difference and decreases in the mean resistance and short-circuit current were noted. In spontaneously secreting mucosae and in histamine-stimulated mucosae after inhibition by 4 mM burimamide, there was a significant decrease in potential difference, but resistance was not significantly changed. The data indicate that the secretory state of the mucosa plays an important role in the ability of the mucosa to withstand H^+ back-diffusion. The absolute quantity of H^+ that leaves the luminal solution may be less important than the quantity of H^+ that can be handled by the tissue at any one time.

6960 ACTIVATION OF PROTEIN KINASE IN THE GUINEA PIG FUNDIC GASTRIC MUCOSA BY HISTAMINE. (Eng.) Wollin, A.; Barnes, L. D.; Hui, Y. S.; Dousa, T. P. (Mayo Clinic Foundation, Rochester, MN). *Life Sci.* 17(8):1303-1306; 1975.

Studies were carried out to determine whether histamine, through mediation by cyclic AMP (cAMP), can activate protein kinase in the intact cells of the gastric mucosa from the guinea pig fundus. Incubation with 10^{-4} M histamine significantly increased the tissue level of cAMP from a mean control level of 14.71 pmol/mg protein to 64.64 pmol/mg protein ($p<0.005$). The (-cAMP/+cAMP) protein kinase activity ratio was increased from a mean control level of 0.739 to 0.897 ($p<0.05$). Protein kinase activity assayed without exogenous cAMP was higher in extracts from tissues exposed to histamine (39.8) than controls (31.2); in contrast, activity assayed in the presence of 5×10^{-6} M cAMP was slightly lower in extracts from histamine-exposed slices than in controls. 1,4-Methylhistamine (10^{-4} M) produced no significant changes in either the tissue level of cAMP or the (-cAMP/+cAMP) protein kinase activity ratio. The results suggest that protein kinase activation is involved in the cAMP-mediated action of histamine on the gastric fundic mucosa.

6961 PARIETAL CELL VAGOTOMY IN DOGS: INFLUENCE ON HEIDENHAIN POUCH ACID SECRETION, SERUM GASTRIN CONCENTRATION, GASTRIC EMPTYING AND MOTILITY. (Eng.) Bone, J.; Brandsborg, O.; Brandsborg, M.; Mikkelsen, K.; Eriksen, P. O.; Amdrup, E. (Kommunehospitalet, 8000 Arhus C, Denmark). *Digestion* 12(4/6):201-208; 1975.

The relations of Heidenhain pouch secretion (i.e., antral hyperfunction) and serum gastrin in six dogs during fasting, after feeding, and before and after parietal cell vagotomy (PCV) were investigated. Gastric motility and emptying were also investigated in the same dogs. There were no significant changes in gastric emptying time before and after the operation. There was a mean 37% increase in the 24-hr Heidenhain pouch secretion following PCV, and this was statistically significant ($p<0.05$) compared to the period before PCV. There was no significant difference between the mean fasting pouch secretion 18 hr before PCV (0.002 mEq/30 min) and that 18 hr after PCV (0.006 mEq/30 min); the mean secretion between the 5th and 10th hr after feeding before PCV (0.025 mEq/5 hr) was not significantly different from that after PCV (0.028

mEq/5 hr). There was a 75% increase in the 5-hr food-stimulated Heidenhain pouch secretion after PCV ($p<0.05$). The increase in pouch secretion after PCV took place mainly in the first 2 hr after the meal. The food-stimulated serum gastrin concentration was also significantly increased after PCV. The maximum serum gastrin concentration was reached at 15 min after feeding, before as well as after PCV. The maximum Heidenhain pouch acid secretion was reached later, at 120 min before and at 90 min after surgery. A significant positive correlation was found between the increase in maximum serum gastrin concentration and Heidenhain pouch secretion after PCV, indicating that up to 80% of the increase in acid output can be explained, yet not necessarily caused, by variations in serum gastrin concentration.

SECRETION AND METABOLISM

Pancreas

6973 SECRETION OF NEW DIGESTIVE ENZYME BY PANCREAS WITH MINIMAL TRANSIT TIME. (Eng.) Rothman, S. S. (Dept. Physiology, Univ. California, San Francisco, CA 94143). *Am. J. Physiol.* 230(6):1499-1503; 1976.

Radioactive leucine was added to whole rabbit pancreas *in vitro* to determine whether the digestive enzymes in acinar cell cytoplasm come from the ribosomes. A small amount of labeled digestive enzyme was secreted within 5 min after adding 25 µCi L-^{14}C-leucine to the isolated gland. This rapid secretion of labeled protein suggests that some new protein is able to bypass intracellular storage pools and is secreted immediately. The secretion of protein overall was inversely related to labeled protein secretion. The average contribution of protein that was secreted immediately to total protein secretion was calculated to be a mean of 2.5%. The mean transit time for the secretion of new protein was estimated to be 2.2 min. When methacholine chloride (1.0 mg/100 ml) was added to the bathing medium, the rate of secretion of the labeled protein was decreased by half. The results are consistent with the hypothesis that this rapidly secreted protein comes directly from the ribosomes via the cytoplasm.

6974 THE ROLE OF EXTRACELLULAR Ca^{2+} AND CYCLIC NUCLEOTIDES IN THE MECHANISM OF ENZYME SECRETION FROM THE CAT PANCREAS.

(Eng.) Schulz, I. (Max-Planck-Institut fur Biophysik, Kennedyallee 70, D-6000 Frankfurt am Main, W. Germany). *Pfluegers Arch.* 360:165-181; 1975.

The role of Ca^{2+}, cyclic AMP (cAMP), cyclic guanosine monophosphate (cGMP), and their dibutyryl analogs on the enzyme secretion from the isolated, perfused pancreas of the cat were studied, along with the interrelation of Ca^{2+} and these nucleotides. Enzyme secretion was stimulated by single rapid injections of several different volumes (amounting to 14-102 μmol Ca^{2+}) of a 110 mM $CaCl_2$ solution; 0.43 U pancreozymin; 65 ng acetylcholine; 4.3 μmol each of dibutyryl cyclic AMP (dbcAMP), dbcGMP, cAMP, ATP, and ADP; 4.7 mol theophylline; and 25 or 47 mol of a 110 mM EGTA solution. Atropine sulfate (10^{-6} M) was also added to the perfusion solution. There was a linear relation between protein or amylase output and the peak Ca^{2+} concentration in the effluent perfusate of 18 mEq/l, which corresponds to a Ca^{2+} ion activity of 14 mEq/l. With higher doses of $CaCl_2$, responses were in the same range as those elicited by injections of acetylcholine or pancreozymin, which have half the maximal stimulation of enzyme secretion. Injections of Ca^{2+} potentiated the effects of dbcAMP, dbcGMP, or theophylline. Infusion of low doses of pancreozymin (0.025 U/min) increased the Ca^{2+} effect by 260%. The findings indicate that extracellular Ca^{2+} is involved in the mechanism of enzyme secretion and that Ca^{2+} and cyclic nucleotides have a synergistic action on the isolated, perfused cat pancreas.

6975 THE RELATION BETWEEN BILE AND PANCREATIC SECRETION IN DOGS AFTER ADMINISTRATION OF A SUB-MAXIMAL DOSE OF 2-DEOXY-D-GLUCOSE.

(Ger.) Nowak, W.; Sill, U.; Lippert, H.; Reding, R. (Chirurgische Klinik, Ernst-Moritz-Arndt-Universitat, Greifswald, E. Germany). *Scr. Med.* 48(6/7):463-473; 1975.

The effect of 2-deoxy-d-glucose (DG) on the interrelation between bile and pancreatic secretion was examined. Five dogs received 50 mg DG, i.v., and the pancreatic, duodenal, and gastric juice was collected for 150 min via Y cannulation 21 days after the appropriate end-to-end anastomosis. At 15-min intervals, under fasting conditions, the duodenal bilirubin (mg) was significantly correlated (p=0.01) with pancreatic secretion (ml), protein (mg), and HCO_3 (μEq); the correlation of protein in pancreatic secretion and duodenal bilirubin was most prominent, with a regression coefficient of 0.460. Gastric secretion was elevated about 700% over basal levels, 60 min after DG treatment; pancreatic and duodenal secretion rose or fell indifferently. At 15-min intervals after DG administration, duodenal bilirubin (mg) correlated significantly with pancreatic secretion (p=0.05), protein (mg) in pancreatic secretion (p=0.01), and HCO_3 (μEq, p=0.05); the protein-bilirubin correlated especially highly, with a regression coefficient of 0.535. This outcome suggests that more protein is released in pancreatic secretion after vagal stimulation with DG in response to a certain amount of bile (bilirubin). The average duodenal pH during the experiment was 7.0 (5.03-8.07), which excludes acid-associated endogenous secretin liberation. Accordingly, it is probable that duodenal gastrin secretion is the mediator of bile stimulation of pancreatic secretion.

6976 ON THE INTERACTIONS BETWEEN PANCREATIC LIPASE AND COLIPASE AND THE SUBSTRATE, AND THE IMPORTANCE OF BILE SALTS.

(Eng.) Borgstrom, B. (Dept. Physiological Chemistry, Univ. Lund, Lund, Sweden). *J. Lipid Res.* 16(6):411-417; 1975.

The effect of bile salts on the interactions among pancreatic lipase and colipase and the substrate tributyrin (TB) was investigated. Lipase (10 pmol), colipase, (50 pmol), or both were preincubated with 500 μl of TB in 15 ml pH 7.0 buffer in the absence or presence of 4 mM deoxycholyltaurine (DCT). Similar experiments in which hexadecane was substituted for TB and the pH was varied (4.5-9.0) were performed. At pH 7, bile salts prevented the binding of lipase to its substrate, but colipase in the substrate-water interface promoted lipase binding. The results suggest that lipase has an affinity for and binds to hydrophobic interfaces with partial irreversible inactivation. Bile salts in the range of micellar concentrations and above pH 6.5 displaced lipase from this binding, resulting in a reversible inactivation. At pH below 6.5, lipase bound strongly to the substrate even in the presence of bile salts, and a low activity peak was seen around pH 5.5. This is the result of binding to the substrate interface or "supersubstrate," and the activity of the catalytic site. With bile salts, colipase promotes the binding of lipase to this supersubstrate but not to other hydrophobic interfaces, and catalytic activity is reestablished. Kinetic data indicate that the binding between colipase and lipase in the presence of substrate is strong and is stoichiometric.

6977 A MODEL TO STUDY ACUTE PANCREATITIS IN THE DOG.

(Eng.) Musa, B. E.; Nelson, A. W.; Gillette, E. L.; Ferguson, H. L.; Lumb, W. V. (Surgical Lab., Dept. Clinical Sciences, Coll. Veterinary Medicine and Biomedical Sciences, Colorado State

Univ., Fort Collins, CO 80523). *J. Surg. Res.* 21 (1):51-56; 1976.

An acute pancreatitis model was developed in the dog that was consistently lethal and that allowed assessment of the excretory function of the pancreas without catheterization of the pancreatic ducts. The minor pancreatic duct was ligated and cut; a modified Thomas cannula was inserted in the duodenum opposite the major pancreatic duct and exteriorized on the right ventrolateral abdominal wall. This allowed production of pancreatitis by retrograde injection of a bile-trypsin mixture in the major duct. The minimum lethal dose of this mixture, determined in 22 dogs, was 1.02 ml of bile/kg body weight (it was uniformly fatal within 24 hr); there were 2000 U trypsin in each 1 ml of bile used. Injection of this mixture into the major pancreatic duct resulted in severe damage to approximately 38% of the gland. A plastic sleeve was inserted into the cannula during collections of pancreatic juice, isolating the pancreatic duct from the intestine. Secretions could be collected without significant contamination by intestinal content, and minimum cooperation was required from the dog. When the cannula is installed properly, there is no leakage and the dogs tolerate its presence without the need for retraining devices or restriction of activity postsurgery.

6978 ISOLATED PERFUSED RAT PANCREAS AS AN EXPERIMENTAL MODEL FOR THE STUDY OF PANCREATIC SECRETAGOGUES: EFFECTS OF SECRETIN, CCK-PZ, AND VIP [Abstract]. (Eng.) SECRETION AND METABOLISM

Hepatobiliary Tract

6983 SIMILARITIES OF THE GOLGI APPARATUS MEMBRANE AND THE PLASMA MEMBRANE IN RAT LIVER CELLS. (Eng.) Hodson, S.; Brenchley, G. (Unit of Electron Microscopy, Welsh Natl. Sch. Medicine, Heath Park, Cardiff CF4 4XN, United Kingdom). *J. Cell Sci.* 20(1):167-182; 1976.

The protein subunit compositions of a Golgi apparatus-rich fraction (G fraction) and a plasma membrane-rich fraction (PM fraction) prepared from a common homogenate of Wistar rat liver are compared. The G fraction was collected in the density range 1.108 to 1.137 g/cm^3 and the PM fraction was collected in the 1.154 to 1.175 g cm^{-3} range. The homogenate and all fractions were assayed for enzymic activity. The G fraction had the characteristics of high yield and high purity. Galactosyltransferase activity was mainly confined (>95%) to the G fraction. Most of the remaining activity was found in the intermediate fraction. The yield of membrane protein in the G fraction was 2.26 mg protein/g liver. Electron microscopic examination of many sections confirmed the purity of the G fraction. The PM fraction showed no visual or enzyme activity parameters similar to the G fraction. Galactosyltransferase activity was nearly undetectable and was <1%

of the specific activity of the G fraction. Gel electrophoresis of the two fractions showed a close similarity, and in 1/12 cases, a complete identity of the protein subunit patterns. The identity consisted of not only of the R_f values but also of each of the seven major band's staining capacity with Coomassie brilliant blue. It is suggested that there is an intimate relation between the two membranes.

6984 THE EXISTENCE OF A SECOND ROUTE FOR THE TRANSFER OF CERTAIN GLYCOPROTEINS FROM THE CIRCULATION INTO THE LIVER.

(Eng.) Stockert, R. J.; Morell, A. G.; Scheinberg, I. H. (Div. Genetic Medicine, Dept. Medicine, Albert Einstein Coll. Medicine, Bronx, NY 10461). *Biochem. Biophys. Res. Commun.* 68(3):988-993; 1976.

The existence in rats of a second route by which at least one modified glycoprotein, in which N-acetylglucosaminyl residues have been made terminal, is transferred rapidly from the circulation into the liver is described. Male albino rats (250-300 g) were inoculated i.v. with ^{125}I-labeled orosomucoid (OR; α_1-acid glycoprotein) derivatives (5 μg), with or without the addition of an unlabeled glycoprotein (5 mg). The intravascular survival time of the various glycoproteins was determined every 3 min up to 27 min, and radioactivity was assayed in the blood, liver, and kidneys 15 min after injection. The physiological half-life of labeled asialo-OR was between 1 and 2 min, but the simultaneous infusion of unlabeled asialo-OR prolonged the half-life to 37 min by overloading the removal route. The same effect was seen with agalacto-OR. The infusion of unlabeled agalacto-OR negligibly lengthened the half-life of ^{125}I-labeled asialo-OR. In the reciprocal experiment, unlabeled asialo-OR affected the half-life of labeled agalacto-OR insignificantly. The agalacto derivatives of ceruloplasmin (CPN) and OR differed with respect to the duration of their intravascular survival, in contrast to the asialo derivatives of both proteins. Fifteen minutes after injection, 43% of agalacto-CPN, but only 4% of agalacto-OR, remained in the blood; asialo-CPN and asialo-OR were removed from the circulation and taken up by the liver to the same extent. Since the carbohydrate chains of agalacto-OR, from which sialic acid and galactose were sequentially removed, terminate in N-acetylglucosaminyl residues, it is assumed that there is a second hepatic receptor specific for glycoproteins terminating in these residues. This hypothesis is consistent with the fact that only a small proportion of injected, labeled ahexosamino-OR is transferred into the liver and almost half of it is found in the kidneys.

6985 SEPARATION OF KUPFFER AND ENDOTHELIAL CELLS OF THE RAT LIVER BY CENTRIFUGAL ELUTRIATION.

(Eng.) Knook, D. L.; Sleyster, E. Ch. (Inst. Experimental Gerontology TNO, Rijswijk, Netherlands). *Exp. Cell Res.* 99(2):444-449; 1976.

A separation procedure for purified fractions of Kupffer cells on endothelial cells is described and the distribution of some lysosomal enzymes was measured. Nonparenchymal liver cells were isolated from 3-month-old female BN/BiRij rats and were separated by centrifugal elutriation into two fractions consisting of structurally intact Kupffer and endothelial cells with purities of 91 and 95%, resp. Purified Kupffer and endothelial cells showed nearly equal specific activities for the lysosomal enzyme, acid phosphatase (86.6 ± 4.8 and 97.5 ± 7.6 mg protein, resp.); the specific activity of cathepsin D was about three times higher in Kupffer cells (18.0 ± 2.9 versus 6.1 ± 1.2 mg protein). Based on the protein contents of Kupffer and endothelial cells per g of liver (1.48 mg protein and 1.70 mg protein, resp.) and on the threefold difference in their cathepsin D activities, about 13% of the total cathepsin D activity in the liver is present in Kupffer cells, which represent only 0.7% of the total amount of liver protein. The selective enrichment of cathepsin D, the most important lysosomal enzyme for protein degradation, in Kupffer cells is in full agreement with the important function of Kupffer cells in the clearance of foreign substances from the circulation.

6986 HEPATIC NUCLEASES: EXTRAHEPATIC ORIGIN AND ASSOCIATION OF NEUTRAL LIVER RIBONUCLEASE WITH LYSOSOMES.

(Eng.) Bartholeyns, J.; Peeters-Joris, C.; Baudhuin, P. (U.C.L. 7539 Avenue Hippocrate 75, B-1200 Brussels, Belgium). *Eur. J. Biochem.* 60(2):385-393; 1975.

In view of the neutral pH optimum of neutral liver ribonuclease and of some particularities of its distribution in fractionation experiments, the possibility of an extrahepatic origin of neutral RNase was investigated in rats. Three days following partial pancreatectomy, average decreases in neutral RNase activities were 41% and 29% in the serum and liver, resp. This effect was specific, because no effect was observed on acid RNase, DNase, and acid phosphatase. Following the i.v. injection of 10,000 U of labeled bovine RNase A, some of the enzyme was found to accumulate in the liver, the maximal concentration occurring 1 day after the injection. Because of the rapid elimination of the exogenous enzyme in the urine, only 0.1% of the injected enzyme was found in the liver. The specific radioactivity was higher than expected, 0.6% of the radioactivity being recovered in the liver. Rats were injected with a mixture containing labeled bovine RNase (3,500 U), horseradish peroxidase (80,000 U), invertase (2,000 U), and Triton WR-1339 (1 g/kg) 1 day before sacrifice. Radioactivity associated with exogenous RNase, peroxidase, and invertase had similar distributions, with median equilibrium densities of 1.1820, 1.1754, and 1.1824 g/ml, resp. The corresponding values for acid phosphatase and neutral RNase activity were 1.1504 and 1.2001 g/ml, resp. Uptake of neutral RNase from the plasma could explain the behavior of this enzyme after Triton WR-1339 treatment. Both lysosomal enzymes and neutral RNase were fully activated by hypoosmotic shock and by the addition of digitonin (0.015 mg/mg protein) to the suspension medium, suggesting that the major part of liver neutral RNase is associated with the lysosomal system. These results show that neutral liver RNase is associated with lysosomes, and that this localization is a consequence of the uptake of the enzyme from blood plasma by the liver.

6987 SUBCELLULAR DISTRIBUTION OF s-ADENOSYLMETHIONINE DECARBOXYLASE IN RAT LIVER: EVIDENCE OF DECARBOXYLATION OF s-ADENOSYLMETHIONINE SEPARATE FROM SYNTHESIS OF SPERMIDINE. (Eng.)

Sturman, J. A. (Inst. Basic Res. Mental Retardation, Staten Island, NY). *Biochim. Biophys. Acta* 428(1): 56-69; 1976.

The subcellular distribution of *S*-adenosylmethionine decarboxylase activity was investigated in rat liver homogenates, and the enzyme activity was also determined in supernatant fractions of liver homogenates of various species. Liver homogenates from guinea pig, rabbit, chicken, frog, monkey, and human had no sedimentable *S*-adenosylmethionine decarboxylase activity, whereas homogenates from rat, mouse, gerbil, and ferret all had a fraction of activity, which was only released into the supernatant fraction by Triton X-100. Subcellular fractionation of rat liver homogenates revealed that 79.4% of the *S*-adenosylmethionine decarboxylase activity was located in the crude nuclear fraction, while 18.8% occurred in the supernatant fraction. This distribution was not paralleled by the activity of the cytoplasmic enzyme lactate dehydrogenase. The finding of essentially unchanged nuclei in the crude nuclear fraction of a rat liver homogenate prepared in sucrose containing 1% Triton X-100 indicated that the activity was not associated with nuclei, since this fraction contained no activity of *S*-adenosylmethionine decarboxylase. Purified preparations of rat liver nuclei contained little or no detectable activity of *S*-adenosylmethionine decarboxylase, confirming that the activity present in the crude nuclear fraction is not associated with the nuclei, and suggesting that it is associated with the membrane fragments. The large portion of *S*-adenosylmethionine decarboxylase activity, located in the crude nuclear fraction of the rat liver homogenate, was not accompanied by any activity of spermidine synthase. This suggests the existence of an enzyme that decarboxylates *S*-adenosylmethionine and yet does not synthesize spermidine.

6988 ESTROGEN RECEPTOR IN THE MAMMALIAN LIVER. (Eng.)

Eisenfeld, A. J.; Aten, R.; Weinberger, M.; Haselbacher, G.; Halpern, K.; Krakoff, L. (Yale Univ. Sch. Medicine, New Haven, CT 06510). *Science* 191(4229):862-865; 1976.

^{3}H-estradiol binding proteins were found in the supernatant fraction of adult mammalian livers. The supernatant fractions of liver homogenates obtained from adult female Charles River CD rats were incubated with 2×10^{-9} M radioactive estradiol for 1 hr. Six percent of the ^{3}H-estradiol was bound. The addition of nonradioactive estrogens to the incubation medium reduced the binding of the labeled estradiol, while androgens, progesterone, and glucocorticoids did not. The most effective competitors were estradiol, 17α-ethinyl estradiol, and diethylstilbestrol, which reduced the binding to 8.5%, 6.6%, and 10% of the controls, resp. These results indicate that the estradiol binding in the liver is highly estrogen-specific. Radioactive estradiol was incubated with liver slices, and the macromolecular binding in the supernatant and in an extract of highly purified nuclei was measured. Temperature-dependent macromolecular binding in the nucleus was found to be present, the mean level of bound radioactivity in the nucleus at 0 C being 1,400 disintegrations/min (dpm) and that at 25 C being 5,800 dpm. The incubation of liver supernatant, which had previously been incubated with ^{3}H-estradiol, with crude liver chromatin preparations revealed that macromolecular binding to chromatin was dependent on supernatant binding in a temperature-related process. Macromolecules with high affinity for binding estrogen were also found in the liver supernatants of the mouse, rabbit, and green monkey. The binding of estradiol in the liver supernatant was much lower in 27-day-old female rats than in adult rats. When adult and prepubescent female rats received 17α-ethinyl estradiol (100 μg, s.c.), the concentration of the plasma protein renin substrate was increased several-fold in the adults, but was only slightly changed in the prepubescent rats. The estrogen-binding macromolecule in the liver supernatant may be an estrogen receptor that modulates hepatic synthesis of plasma proteins and may be involved in mediating the serious side effects seen in women using estrogen-containing contraceptives.

6989 SYNTHESIS AND HALF-LIFE OF A SERUM FACTOR IN NORMAL AND TUMOR-BEARING ANIMALS.

(Eng.) Dolan, M. L.; Sudbury, B.; Ove, P. (Univ. Pittsburgh Sch. Medicine, Pittsburgh, PA 15261). *J. Natl. Cancer Inst.* 56(6):1261-1267; 1976.

A serum factor found in normal rats is known to disappear from the sera of hepatoma-bearing rats and rats maintained on a low-protein diet; the hypothesis that this factor is synthesized in the liver in normal and hepatoma-bearing rats and disappears because of an increased demand for it by the growing number of hepatoma cells was tested. Normal and Morris hepatoma 7777-bearing male BUF rats received a 10-min pulse of ^{3}H-leucine (100 μCi/100 g, i.v.). The mean rate of synthesis of the serum factor in the host liver after 10 min (23.1 counts/min/μg) was twice that found in the normal liver (11.5 counts/min/μg), despite very low levels in the sera of tumor-bearing animals. The counts recovered in the serum factor-antibody complex were not due to nonspecific binding, as indicated by the absence of counts when the animals were given cycloheximide (2 mg/100 g) 10 min prior to the injection of ^{3}H-leucine. All the counts from the complex were associated with the 39,000 molecular weight band, representing factor subunits after sodium dodecyl sulfate gel electrophoresis. About twice as much serum factor was associated with the microsomes of the host liver (8.8 μg serum factor/mg microsomal protein) as with those of the normal liver (4.6 μg/mg). Half-lives of the serum factor and total serum protein were determined using an antifactor immunoglobulin G affinity column. The half-life of the total serum protein was 2 days in normal rats and 2.9 days in hepatoma-bearing animals; the half-life of the serum factor was 23 hr in normal rats but only 9 hr in hepatoma-bearing ones. This rapid disappearance of the factor from the circulating blood, despite an increased synthesis, accounts for the complete absence of the factor in the sera of hepatoma-bearing animals with tumor weights larger than the liver weights.

6990 HEPATOCYTE PERFUSION WITHIN A CENTRIFUGE. (Eng.) Eiseman, B.; Norton, L.; Kralios, N. C. (Denver General Hosp., Denver, CO). *Surg. Gynecol. Obstet.* 142(1):21-28; 1976.

The use of RBC washing centrifuge units as perfusion chambers for hepatocyte suspensions being evaluated for potential extracorporeal liver support is described. Two types of centrifuge unit were used, a unit requiring intermittent perfusion and a continuous-flow unit. With the former unit, 30-190 g of living hepatocytes from pigs were perfused with 900-1,000 ml of 100% cell-free oxygenated (pO_2, 300 mm Hg) swine serum. Cell viability, as reflected by trypan blue exclusion, both started and remained above 90% in 6 of 11 experiments. However, $2\text{-}^{14}C$-labeled pyruvate metabolism progressively deteriorated during the 2- to 3-hr perfusion experiments. In addition, oxygen consumption began a progressive deterioration as the hypoxic cells failed to survive on their intermittent supply of oxygenated perfusate. In contrast, a continuous-flow unit could, at a flow of 800 ml of human plasma per min, support most functions of 100 g of pig hepatocytes for 6 hr, and some functions for 12 hr. In 12 of 18 experiments, trypan blue viability remained above 85%, and this included one experiment lasting 12 hr. In three studies, an initial low viability of 20-70% increased to above 95% within 15 min of perfusion and remained at that level throughout the experiment. The rate of $2\text{-}^{14}C$-labeled pyruvate metabolism decreased progressively in each study; by the 2nd-4th hour, the metabolism was above 50% of the initial rate in two experiments, less than 50% in five studies, less than 25% in five studies, and less than 10% in one study. At 15 min of perfusion, the mean oxygen consumption was 35% of the theoretic normal of 0.04 ml O_2/g hepatocytes/min. Thereafter, the mean peak utilization was 74% at 78 min. The results show that the oxygen needs of hepatocytes are so great, and the dissolved oxygen in plasma is so small, that a continuous perfusion unit is necessary to avoid lethal levels of hypoxia. A centrifuge allowing constant perfusion of oxygenated plasma into hepatocytes kept within the unit by centrifugal force is a suitable base for extracorporeal liver support.

6991 HEPATIC PROLYL HYDROXYLASE ACTIVITY IN EXPERIMENTAL CIRRHOSIS. (Eng.) McPhie, J. L.; Short, L. T. (Dept. Pathology, Univ. Aberdeen, Aberdeen, Scotland). *Acta Hepatogastroenterol. (Stuttg.)* 22(6):387-391; 1975.

Hepatic collagen synthesis was investigated during progressive fibrosis induced by carbon tetrachloride (CCl_4) in male Sprague-Dawley rats by determining the prolyl hydroxylase activity and hydroxylproline levels and assessing the fibrosis morphologically. Hepatic cirrhosis was induced within 4 weeks by periodic inhalation of CCl_4 vapor. Prolyl hydroxylase activity and hydroxylproline content were estimated at various times. When compared with the morphological features, enzyme activity became elevated when hepatocellular necrosis supervened upon the initial features of fatty change in the hepatocytes (week 2). Thereafter, activity increased with progression to visible fibrosis (at 2.5 weeks) and ultimate cirrhosis (at 3.5 weeks) and remained elevated, reaching a maximum (745 cpm/mg protein) over three times the control value after 5 weeks. Hydroxylproline levels lagged behind the increasing enzyme activity and were not significantly increased (to 8.2 μmol/mg wet weight) until week 3. The early elevation of hydroxylase activity at a time when the dominant feature is hepatocellular necrosis suggests that the collagen-stimulating factors recovered from mouse liver acutely damaged by CCl_4 ingestion may represent factors released from necrotic hepatocytes.

6992 HEPATIC ERYTHROPOIETIN: ENHANCED PRODUCTION IN ANEPHRIC RATS WITH HYPERPLASIA OF KUPFFER CELLS. (Eng.) Peschle, C.; Marone, G.; Genovese, A.; Magli, C.; Condorelli, M. (Istituto Patologia Medica, Nuovo Policlinico, Via S. Pansini, 80131 Naples, Italy). *Br. J. Haematol.* 32(1):105-111; 1976.

In an attempt to evaluate the role of the reticuloendothelial system (RES) as a possible source of erythropoietin (Ep), Ep levels were assayed in the serum of adult male Wistar rats subjected sequentially to the i.v. administration of colloidal carbon (1.0 ml/250 g, 4 days), zymosan (5 mg/200 g, 4 x), or their vehicles; sham operation or bilateral nephrectomy with and without subtotal hepatectomy; and hypoxia (0.45-0.40 atmospheres of air for 6 hr starting 1 hr after the operation). In anephric rats, colloidal carbon induced a significant potentiation of hypoxic Ep activity (26.48% ^{59}Fe-RBC incorporated) in comparison to that in controls receiving saline (13.73% ^{59}Fe-RBC incorporated) or the vehicle (14.46% incorporated). Zymosan also potentiated hypoxic Ep activity (15.62% incorporated), in comparison with the activity in the vehicle-treated animals (9.08% incorporated). Since the two agents did not apparently modify the kinetics of exogenous Ep, it is postulated that this phenomenon is mediated by enhanced extrarenal Ep production. Both colloidal carbon and zymosan induced hyperplasia of the RES. Moreover, subtotal hepatectomy almost abolished the Ep response to hypoxia evoked by zymosan. The correlation between hyperplasia of hepatic RES and enhanced Ep production in anephric rats primed with these agents suggests that Kupffer cells constitute a major source for extrarenal Ep. It is of interest that colloidal carbon and zymosan did not significantly modify the renal production of Ep.

6993 CIRCADIAN RHYTHM OF BILIARY EXCRETION AND ITS CONTROL MECHANISMS IN RATS WITH CHRONIC BILIARY DRAINAGE. (Eng.) Ho, K.-J.; Drummond, J. L. (Dept. Pathology, Univ. Alabama, Birmingham, AL 35294). *Am. J. Physiol.* 229(5):1427-1437; 1975.

The circadian rhythm of biliary excretion and its control mechanisms were investigated in Sprague-Dawley rats with chronic biliary drainage. Rats were kept under a rigid lighting schedule (light on at 6 a.m. and off at 6 p.m.) and fed either a standard diet (24 rats) or the diet supplemented with 2% cholesterol (8 rats). A permanent bile fistula was made in all rats, and the animals were divided into four groups: control (6), cholesterol-fed (8), vagotomy (8), and adrenalectomy (10). Vagotomy and adrenalectomy were performed at the same time as the fistula. The rats exhibited a remarkable circadian rhythm of bile flow, biliary concentrations, and excretory rates of bile salt, cholesterol, and phospholipid. The peak was attained at midnight and the nadir at noon, except for peak and nadir concentrations of cholesterol and phospholipid occurring at 8 p.m. and 8 a.m., resp. Cholesterol feeding abolished the circadian rhythm of biliary cholesterol and phospholipid concentrations, but not their excretory rates, because the daily fluctuation of the bile flow remained unchanged. Bilateral vagotomy enhanced the bile flow rate and shifted the peak for all parameters except bile salt to 4 hr earlier. Bilateral adrenalectomy abolished the rhythm of the concentration of cholesterol and phospholipid and minimized that of bile salt, but the daily fluctuation of their excretory rates persisted in a lower amplitude. The studies suggest that this circadian rhythm might be controlled simultaneously by multiple factors, as it could not be entirely abolished by any single special treatment.

6994 THE LYMPHATIC DRAINAGE OF THE LIVER CAPSULA AND HEPATIC PARENCHYMA. (Eng.)

Szabo, G.; Magyar, Z.; Jakab, F. (Zentralinstitut fur Traumatologie, H-1430 Budapest VIII, Mezo Imre ut 17, Hungary). *Res. Exp. Med. (Berl.)* 166(2): 193-200; 1975.

The lymphatics transport of bilirubin and of ^{131}I-albumin absorbed from the liver capsule was studied in dogs during the early stage of complete biliary obstruction by common bile duct occlusion. Bilirubin transport by the right lymph trunk (0.86 μg/min) was only 1.6% of that by the thoracic duct (51.49 μg/min). The total amount of bilirubin transported was 2.41 and 7.09 mg%, resp. Labeled albumin absorbed from the liver capsule was transported by both the right lymph and thoracic ducts. In a further series of experiments, labeled albumin was infused into the common bile duct under high pressure to open up nonfunctioning connections between the intraparenchymatous lymphatics and the superficial vessels. This procedure was repeated after ligation of the lymph vessels in the hepatic hilum. During the infusion, albumin was transported from the liver parenchyma almost exclusively by the thoracic duct. After the occlusion of about 70% of the lymphatics draining the liver, the increase in albumin transport by the right duct accounted for only an insignificant fraction of the loss from the thoracic duct lymph. It is concluded that lymph formed in the hepatic parenchyma is transported by vessels joining the thoracic duct. Capsular lymphatics run to both the thoracic and right lymph ducts. There is almost a complete division of function between the superficial and deep lymphatics of the liver.

6995 METABOLISM OF 1-^{3}H-ETHANOL BY ISOLATED LIVER CELLS. TIME-COURSE OF THE TRANSFER OF TRITIUM FROM *R,S*-^{3}H-ETHANOL TO LACTATE AND β-HYDROXYBUTYRATE. (Eng.)

Grunnet, N.; Thieden, H. I. D.; Quistorff, B. (Dept. Biochemistry A, Panuminstituttet, Blegdamsvej 3c, DK-2200, Copenhagen N, Denmark). *Acta Chem. Scand.* [*B*] 30(4):345-352; 1976.

The amount of acetaldehyde oxidized in the extramitochondrial cell compartment at physiological concentrations of acetaldehyde was investigated in the isolated liver cells of female Wistar rats. Parenchymal cells of 24-hr-fasted rats were incubated with 65 mM *R,S*-1-^{3}H-ethanol plus 3 mM pyruvate as substrates in the absence and presence of 4-methylpyrazole (1.7 mM). Metabolite levels and the time course of the transfer of tritium from ethanol to lactate and β-hydroxybutyrate was measured during the first 15 min of ethanol metabolism. The time course of the loss of tritium from 2-^{3}H-L-lactate and 3-^{3}H-β-D-hydroxybutyrate in identical experiments was also measured. The incorporation rate of tritium from ethanol into lactate and β-hydroxybutyrate decreased with time. The addition of 4-methylpyrazole decreased the incorporation rate roughly proportional to the decrease in ethanol and acetaldehyde metabolism. The incorporation rates of tritium to lactate were corrected for the detritiation rates measured in experiments with 2-^{3}H-L-lactate and 3-^{3}H-β-D-hydroxybutyrate as substrates. The rate of extramitochondrial acetaldehyde oxidation for the present experimental conditions was calculated from the corrected initial rates of incorporation of tritium into lactate to range from 0-0.4 μmol/min/ml of cells.

6996 INACTIVATION OF ALCOHOL AND RETINOL DEHYDROGENASES BY ACETALDEHYDE AND FORMALDEHYDE.

(Eng.) Grisolia, S.; Guerri, C.; Godfrey, W. (Dept. Biochemistry, Univ. Kansas Medical Center, Kansas City, KS 66103). *Biochem. Biophys. Res. Commun.* 66(4):1112-1117; 1975.

The significance of the effects of aldehyde following ethanol intoxication was pursued in experiments in which alcohol dehydrogenases from horse liver, rat liver, and human retina and retinol dehydrogenase from rat liver were incubated at 37 C with low concentrations of acetaldehyde (AA, 17 and 53 mM) and formaldehyde (FA, 3-29 mM). Activity was assayed at 0, 30, and 60 min. There was a rapid and progressive inactivation of alcohol dehydrogenase and retinol dehydrogenase by AA and FA. The aldehydes inactivated the alcohol dehydrogenase of human retina homogenates markedly; after 1 hr. the activity was reduced from 100% to 10% by 53 mM AA. The enzyme was more sensitive to AA and less sensitive to FA. However. the reverse was true with the liver enzymes--horse liver alcohol dehydrogenase activity was reduced to 10% by 17 mM FA. The effect of FA was tested on other dehydrogenases that contain sulfhydryl groups. Malic dehydrogenase (pig heart), like rat liver alcohol dehydrogenase, was markedly inactivated, but lactic dehydrogenase and glyceraldehyde-3-phosphate dehydrogenase (rabbit muscle) were more stable. To pinpoint the effect of FA on sulfhydryl groups, glutathione (GSH) was added to an incubation mixture containing horse liver alcohol dehydrogenase. High concentrations of GSH

(0.05 M) protected the enzyme against FA inactivation. Moreover, addition of 0.25 M GSH not only prevented further inactivation, it partially restored the activity. The experiments show the great sensitivity of alcohol and retinol dehydrogenases to aldehydes, levels of which can be high in humans after ethanol consumption.

6997 EFFECT OF ETHANOL INTAKE ON THE INCORPORATION OF LABELLED AMINO ACIDS INTO LIVER PROTEIN.

(Eng.) Morland, J.; Sjetnan, A. E. (Inst. Medical Biology, Univ. Tromso, N-9001 Tromso, Norway). *Biochem. Pharmacol.* 25(19):2125-2130; 1976.

The effect of ethanol on the incorporation of labeled amino acids into liver protein was studied in male Wistar rats receiving ethanol as approximately 30% of their total caloric intake. Sucrose or lipids replaced ethanol isocalorically in controls. Ten percent of the calories were usually provided by protein, except in one experiment in which both treated and control animals received 25% of their calories from protein. The diets were given for periods of up to 35 days. When ethanol replaced sucrose isocalorically, the incorporation of labeled amino acids into liver cell protein was reduced by 18.5% after treatment for 30 days, but not after treatment for 1 or 3 days. The reduced incorporation was present both in the presence of ethanol and 24 hr after the last intake of alcohol. When ethanol replaced lipids isocalorically, the same reduction of protein labeling was found as when sucrose was replaced, after treatment for 35 days. When both ethanol-treated and control animals were given a protein-rich diet for 35 days, ethanol treatment caused the same reduction of amino acid incorporation into protein, as when both groups were fed a low-protein diet. It is concluded that long-term ethanol treatment mediates a reduction of protein synthesis in the liver. This reduction requires some time to develop, is due to the inclusion of ethanol in the diet, and is not counteracted by a high-protein diet.

6998 THE EFFECT OF DIET AND ALCOHOL ON THE DEVELOPMENT OF FOLATE DEFICIENCY IN THE RAT.

(Eng.) McGuffin, R.; Goff, P.; Hillman, R. S. (Univ. Washington Medical Sch., Seattle, WA 98195). *Br. J. Haematol.* 31(2):185-192; 1975.

Studies of the rate of depletion of serum and tissue methylated and nonmethylated folates were conducted with female Sprague-Dawley rats maintained for long periods on either a folate-deficient diet or a folate-deficient diet plus high alcohol intake. Folate deficiency was induced by restricting animals to a liquid diet of 25% sucrose in water to which 100 mg succinylsulphathiazole/100 ml was added to suppress the intestinal production of folates. Constant blood ethanol levels of between 50 and 300 mg/dl were maintained for 3-4 weeks by the administration of 100 ml/kg of 10% ethanol in three or four divided doses through a surgically placed gastrostomy tube. Using this animal model, which closely resembles severe alcoholism in man, a rapid depression in 5-methyltetrahydropteroyl glutamates, one to seven (5-methyl H_4 PteGlu 1-7), was observed similar to that reported in alcoholic men. The serum values of these methylated folates in folate-starved animals treated with alcohol had fallen below 30% of the original value by the third day of treatment, while animals on folate-deficient, sugar-water diets maintained levels greater than 60% of the original value. This difference continued for 8 days, until the serum 5-methyl H_4 PteGlu values for both groups had fallen to below 30% of the original values. Ethanol did not alter the rate of depletion of liver methylated and nonmethylated folate stores from that observed in folate-starved, sucrose-water control animals. Whatever the effect of ethanol on serum 5-methyl H_4 PteGlu levels, the rapid depression in serum values is not related to a gross change in liver pool kinetics, such as a major block in the release of 5-methyl H_4 PteGlu from liver polyglutamate stores.

6999 AZATHIOPRINE HEPATOTOXICITY, DIRECT COMPLICATION OR SECONDARY EFFECT IN RAT LIVER TRANSPLANTATION.

(Eng.) Hess, F.; Jerusalem, C.; Polak, M. (Univ. Nijmegen, Lab. Cytology and Histology, Geert Grooteplein Noord 21, Nijmegen, Netherlands). *Eur. Surg. Res.* 8(2):156-165; 1976.

The risk of azathioprine-induced hepatocellular damage was investigated using an auxiliary liver iso- and allotransplantation model in PVG/C and Wistar rats. The model permits study of the drug effect on both the graft and the recipient livers, which are vascularized in different ways. Rats underwent allotransplantation (PVG/C to Wistar), isotransplantation (Wistar to Wistar), or subtotal (70%) hepatectomy plus ligation of the hepatic artery (Wistar). Treated rats received 10 mg/kg/day azathioprine (10 mg/kg/day, i.v.) for 20 days. Neither histopathological changes nor deaths directly attributable to drug toxicity to the hepatocytes were found. All livers of azathioprine-treated animals exhibited pronounced, but differing, morphological changes that depended on the surgical procedures and immunosuppressive therapy, if any. In the untreated isologous transplant group, the host liver exhibited temporarily scattered small foci of parenchymal necrosis, probably due to a high local concentration of biliary acids. Morphological lesions were absent in the treated and untreated subtotally hepatectomized rats with normal bile flow. Lesions did become manifest after reimplantation (grafts) and/or ligation of the common bile duct (hosts). It is concluded that in rats, azathioprine is toxic for hepatocytes only when the normal bile flow is impeded, independent of the type of liver vascularization.

7000 IMPAIRED LITHOCHOLATE SULFATION IN THE RHESUS MONKEY: A POSSIBLE MECHANISM FOR CHENODEOXYCHOLATE TOXICITY.

(Eng.) Gadacz, T. R.; Allan, R. N.; Mack, E.; Hofmann, A. F. (Dept. Surgery, Johns Hopkins Univ. Sch. Medicine, Baltimore, MD 21205). *Gastroenterology* 70(6):1125-1129; 1976.

The ability of the rhesus monkey to sulfate a tracer dose of lithocholate during a single hepatic passage was investigated to determine lithocholate metabolism in this species. Radioactive lithocholase (5 μCi) alone or with 10 μCi 11,12-^{3}H-chenodeoxycholic acid or 10 μCi 11,12-^{3}H-sulfolithocholylglycine was administered i.v. to female monkeys with an exteriorized enterohepatic circulation, and the chemical form of biliary radioactivity was defined by thin-layer chromatography. A total of 70%-92% of injected radioactivity was recovered in the bile over 4 hr. Little radioactivity was excreted in urine. When conjugated lithocholate was injected, most biliary radioactivity (77%) was excreted in products having the chromatographic mobility of lithocholylglycine or lithocholyltaurine, indicating impaired sulfation relative to man. Only 17% had the mobility of sulfolithocholylglycine or sulfolithocholyltaurine. Sulfolithocholylglycine was excreted in the bile virtually unchanged, although 12.5% of the recovered radioactivity had the mobility of lithocholylglycine or lithocholyltaurine, suggesting some desulfation during hepatic passage. Chenic acid was excreted mostly (89%) as chenylglycine or chenyltaurine. Biliary composition by gas-liquid chromatography was largely cholate. These experiments indicate that the major bacterial biotransformation product of chenic acid is not readily sulfated, and probably not detoxified, in the female rhesus monkey as it is in man.

7001 EFFECTS OF CHRONIC ADMINISTRATION OF POLYBROMINATED BIPHENYLS ON PARAMETERS ASSOCIATED WITH HEPATIC DRUG METABOLISM.

(Eng.) Dent, J. G.; Netter, K. J.; Gibson, J. E. (Pharmakologisches Institut der Universitat D-6500 Mainz, W. Germany). *Res. Commun. Chem. Pathol. Pharmacol.* 13(1):75-82; 1976.

Parameters associated with hepatic microsomal drug metabolism were measured *in vitro* following the exposure of female Sprague-Dawley rats to polybrominated biphenyls (PBB) as a dietary supplement (4.69, 18.75, 75, and 300 ppm) for 2 weeks. The food consumption and growth rate of animals was not affected by PBB, but significant increases in hepatic drug metabolism over control levels were observed. The amount of microsomal protein was increased significantly to 152% of the control value, by both 75 and 300 ppm PBB in the diet ($p<0.05$). Cytochrome P_{450} was increased significantly to 158, 227, and 30% of the control values, by 18.75, 75, and 300 ppm PBB, resp. Cytochrome b_5 was increased to 184 and 205% of control values by the two higher concentrations, resp. The three highest concentrations caused significant increases in ethylmorphine-N-demethylase (230, 434, and 485% of controls, resp.), ethoxycoumarin-O-deethylase (463, 1,076, and 1,601% of controls, resp.), and benzo(a)pyrene hydroxylase (218, 936, and 1,303% of controls, resp.). All four concentrations caused significant increases in epoxide hydratase (134, 167, 211, and 256% of controls, resp.). The increases seen in NADPH-cytochrome c reductase were significant with 18.75 and 300 ppm PBB only (137 and 190% of controls, resp.), and the increases seen in aniline hydroxylase were significant only with 4.69, 75, and 300 ppm PBB (80, 199, and 268% of controls, resp.). The pattern of induction seen after PBB exposure was compared with those produced by phenobarbital (80 mg/kg) or 3-methylcholanthrene (20 mg/kg), which were administered i.p. 3 days prior to sacrifice. Phenobarbital produced significant increases in cytochrome P_{450}, NADPH-cytochrome c reductase, epoxide hydratase, aniline hydroxylase, ethylmorphine-N-demethylase, ethoxycoumarin-O-deethylase, and benzo(a)pyrene hydroxylase, but not in microsomal protein or cytochrome b_5. 3-Methylcholanthrene produced increases only in cytochrome P_{450}, aniline hydroxylase, ethoxycoumarin-O-deethylase, and benzo(a)pyrene hydroxylase. The two higher PBB concentrations, and both phenobarbital and 3-methylcholanthrene, produced a significant increase in the ratio of liver weight to body weight (111 and 144% of controls for 75 and 300 ppm PBB, resp.). The pattern of enzyme induction and spectral characteristics of the induced cytochrome P_{450} indicate that PBB may be similar to both the carcinogenic polycyclic hydrocarbons and the phenobarbital-like agents. PBB could affect the toxicity of other compounds.

7002 THE EFFECT OF A LONG-TERM CCl_4 ACTION ON THE DNA CONTENT OF RAT LIVER CELL NUCLEI. A CYTOPHOTOMETRIC STUDY.

(Eng.) Vitalis, B. (Dept. Biology, Univ. Medical Sch., Pecs, Hungary). *Folia Histochem. Cytochem. (Krakow)* 13(3/4):207-212; 1975.

The effect of long-term carbon tetrachloride (CCl_4) administration on the DNA content of rat liver cell nuclei was investigated in inbred CFY male and female rats. DNA values and ploidy distribution were correlated with the histopathological features of the liver tissue and with the sex of the animals. The animals were inoculated s.c. twice a week with a 50% solution of CCl_4 (0.13 ml/100 g body weight) for 12 weeks). DNA content per interphase nucleus was determined cytophotometrically. The degree of severity and histopathological signs of liver injury were more pronounced in males than in females. The females manifested fatty degeneration around the central veins without fibrosis, but the males developed cirrhosis. The cytophotometric DNA measurements revealed increased numbers of polyploid nuclei, with a mean amount of DNA per nucleus in the diploid range slightly greater than the control value. Two modal peaks were found, one in the diploid and one in the tetraploid range, with a simultaneous occurrence of remarkable numbers of over-tetraploid nuclei. Cell nuclei from normal liver showed a modal peak in the diploid range. There was no second peak in the tetraploid region. The histological patterns of the hepatic lesions varied accordingly to sex, but the ploidy distributions were similar in both sexes. There was no relation between DNA content and the type of histopathological change. The data show that after CCl_4 treatment, the amount of DNA per nucleus increased over the control value, and this was responsible for the appearance of a second peak in the tetraploid range. The ploidy changes in the cell nuclei agreed with previous experiments in which increased DNA synthesis and a high frequency of atypical mitoses were found after chronic CCl_4 intoxication.

7003 BILIARY EXCRETION OF ^{64}Cu, ^{65}Zn AND ^{203}Hg IN THE RAT WITH LIVER INJURY INDUCED BY CCl_4. (Eng.) Cikrt, M.; Tichy, M.; Holusa, R. (Inst. Hygiene Epidemiology, Srobarova 48, 100 42 Prague 10, Czechoslovakia). *Arch. Toxicol. (Berl.)* 34(3):227-236; 1975.

To investigate the possibility that the elimination of toxic metals might be altered in the CCl_4-damaged liver, the kinetics of biliary excretion and the distribution of ^{64}Cu, ^{65}Zn, and ^{203}Hg were studied in 48 female Wistar rats injected s.c. with CCl_4. The animals treated with ^{64}Cu or ^{65}Zn received CCl_4 (1 ml/kg) twice weekly for 3 months, and eight of these rats received an aqueous solution, i.v., of ^{203}Hg 1 month after the CCl_4 exposure was terminated. In addition, BSP excretion was determined in 10 CCl_4-exposed rats and 5 controls. The mean BSP excretion in the rats exposed to CCl_4 was prolonged (6.23 min) in comparison to controls (4.13 min). The mean cumulative biliary excretion of ^{65}Zn, 24 hr after the administration of $^{65}ZnCl_2$ (39 μg Zn^{2+}/rat, i.v.), was significantly higher than that in controls (2.37 versus 0.63% of the administered dose), as was the rate of excretion. Urinary and fecal excretion of ^{65}Zn did not differ significantly in the exposed and control animals. The mean amount of ^{65}Zn in the liver of CCl_4-treated rats (16.8%) was significantly different from that in the controls (20.0%), but the distribution in the kidney, plasma, and the wall of the gastrointestinal tract was not significantly different in the two groups. There were no statistically significant differences in the biliary excretion of ^{64}Cu following the injection of $^{64}CuCl_2$ (40 μg Cu^{2+}/rat, i.v.) in the treated and untreated animals, but the urinary and fecal excretion in the treated rats (3.13 and 4.78, resp.) were significantly higher than those in the untreated controls (1.3 and 2.35%, resp.). The ^{64}Cu content in the liver and kidneys in the treated rats (20.5% and 9.67%, resp.) was significantly higher than in the controls (10.8% and 2.5%, resp.). After the administration of $^{203}HgCl_2$ (120 μg Hg^{2+}/rat, i.v.), the mean cumulative ^{203}Hg biliary excretion in the exposed animals (1.94%) was significantly lower than that in the controls (4.1%). The urinary Hg excretion was similar in the two groups, and the fecal excretion was significantly higher in the exposed rats (2.95%) than that in the controls (1.64%). The ^{203}Hg content in the kidneys of the exposed animals (8.24%) was lower than that in controls (9.6%), and that in the gastrointestinal wall in the exposed group (1.67%) was lower than in controls (2.45%). The results suggest that animals with CCl_4-induced liver damage are capable of utilizing alternate pathways for the excretion of exogenous metals.

7004 INDUCTION AND PREVENTION OF GALACTOSAMINE HEPATITIS. (Eng.) Reutter, W.; Hassels, B.; Lesch, R. *In: New Trends in the Therapy of Liver Diseases. Proceedings of the International Symposium on New Trends in the Therapy of Liver Diseases, Tirrenia, June 6-7, 1974.* (New York: Karger): pp. 121-127; 1975.

The effect of (+)-cyanidanol-3 on the development of galactosamine hepatitis was tested in female Wistar rats, and the induction of hepatitis by galactosamine is reviewed. The administration of D-galactosamine (375 mg/kg) to rats pretreated with (+)-cyanidanol-3 (250 mg/kg) resulted in only slight increases in the mean levels of plasma SGOT (49 mU/ml), sorbitol dehydrogenase (8 mU/ml), and glutamate dehydrogenase (11 mU/ml), whereas these levels in rats treated only with D-galactosamine were significantly elevated (731 mU/ml, 598 mU/ml, and 264 mU/ml, resp.). The mean bilirubin concentration in the pretreated rats (0.12 mg/100 ml) was normal, whereas that in the animals treated only with D-galactosamine was 1.06 mg/100 ml. Lower doses of (+)-cyanidanol-3 (10 and 50 mg/kg) also reduced the liver-damaging effects of D-galactosamine, in a dose-dependent manner. The rate of 1-^{14}C-L leucine (100 μCi/kg, i.p.) incorporation in rats that had been previously treated with D-galactosamine (375 mg/kg) was 35% of the control value. When the rats were also pretreated with (+)-cyanidanol-3 (3 x 250 mg/kg/day), the incorporation rate was also decreased, but only to 50% of the control value. This demonstrates that (+)-cyanidanol-3 interacts with the protein metabolism of the liver plasma membrane.

7005 EFFECTS OF HISTAMINE, VASOPRESSIN, AND ANGIOTENSIN II ON HEPATOSPLANCHNIC HEMODYNAMICS, LIVER FUNCTION, AND HEPATIC METABOLISM IN CATS. (Eng.) Krarup, N. (Inst. Physiology, Univ. Aarhus, Aarhus, Denmark). *Acta Physiol. Scand.* 95 (3):311-317; 1975.

The effects of continuous i.v. infusions of histamine (5 μg/kg/min), vasopressin (10 mU/kg/min), or angiotensin II (0.5 μg/kg/min) on hepatosplanchnic hemodynamics in fasting cats were investigated. Hepatic arterial flow was decreased 30% by histamine and increased 30% by vasopressin, but portal venous flow was increased 25% and decreased 40%, resp. Both were not significantly affected by angiotensin. The hepatic arterial conductance was decreased 25% by histamine and angiotensin and not significantly affected by vasopressin. The gastrointestinal conductance was decreased 40% by vasopressin and angiotensin and increased 25% by histamine. The conductance in the intrahepatic low-pressure vessels was not affected by histamine and vasopressin, but it decreased 25% during angiotensin infusion. These hemodynamic effects were not accompanied by changes in liver function or hepatic metabolism, as judged from the splanchnic elimination of ethanol, the hepatic uptake and excretion of indocyanine green, the hepatic oxygen consumption, and lactate and ketone production.

7006 NUTRITIONAL REGULATION OF LIPID METABOLISM IN RATS VII. EFFECT OF OVERNIGHT FASTING ON LIVER LIPIDS OF RATS FED DIFFERENT LEVELS OF ESSENTIAL FATTY ACIDS. (Eng.) Sugano, M.; Imaizumi, K.; Kamo, F. (Lab. Nutrition Chemistry, Kyushu Univ. Sch. Agriculture, Higashi-ku, Fukuoka 812, Japan). *Nutr. Metab.* 19(1/2):65-72; 1975.

The effect of overnight fasting on the concentration and composition of hepatic lipids was investigated in male Wistar rats fed different levels of essential fatty acids (EFA). The animals were fed either a fat-free diet for 17 days or a diet containing 20% corn oil, 5% corn oil, or 20% lard for 14 days. The mean hepatic triglyceride content was significantly increased in fasted animals on the 5% corn oil diet (23.4 mg/g), in comparison with that in fed controls (13.5 mg/g). The mean concentration of hepatic phospholipid was similar among the controls fed the different diets; fasting produced significant increases in phospholipid concentration in all diets (31.2, 30.4, 32.1, and 28.0 mg/g in controls fed the 20% corn oil, 5% corn oil, 20% lard, or fat-free diets, resp.; 39.3, 41.2, 41.4, and 37.4 mg/g in fasted animals fed the respective diets). The fatty acid composition of triglyceride in the animals fed the 5% corn oil or the 20% lard diets was significantly changed by fasting; the percentages of linoleic and arachidonic acids increased significantly, while those of oleic and palmitoleic acids decreased significantly. Palmitic acid also decreased significantly in the fasted rats fed the 20% lard diet. There was a significant decrease in the percentage of oleic acid and a significant increase in that of arachidonic acid in the phosphatidylcholine from the livers of fasted rats. In the hepatic phosphatidylcholine of fat-fed rats, the percentage of linoleic acid was significantly decreased. The results show that the effect of overnight fasting on the concentration and composition of hepatic lipids differs considerably, depending upon the pool size of EFA in the body.

7007 EFFECT OF DIETARY SUCROSE AND FRUCTOSE ON THE METABOLISM AND LIPID FRACTIONS IN LIVER IN THE RAT. (Eng.) Tuovinen, C. G. R.; Bender, A. E. (Dept. Public Health, 62 Beulah Road, Norwood, South Australia 5067). *Nutr. Metab.* 19 (1/2):1-9; 1975.

Experiments were carried out to determine whether the changes in lipid metabolism and hepatic lipid fractions observed previously in rats fed 60-80% sugars in the diet can be effected at lower proportions of dietary carbohydrate and whether these changes persist on feeding the diets for longer periods of time. Male and female Lister rats were fed one of the following diets for 26 weeks: 60% (weight/weight) starch as control (59% of energy content), 20% sucrose (20% of energy content), 40% sucrose (39% of energy content), 60% sucrose (59% of energy content), or 20% fructose (20% of energy content). Forty and 60% sucrose caused an increase in liver weight in male rats only (control 4.5 g/100 g body weight; 40% sucrose 4.7 g/100 g; 60% sucrose 4.9 g/100 g). In both males and females, 40 and 60% sucrose increased the total lipid content of the liver by 132% and 117%, resp., in the males and by 131% and 112%, resp., in the females (the 3 former values were significant at the 95% confidence level, while the latter value was not significant). These increases were caused primarily by increases in triglycerides, which were significantly higher than in controls (186% and 154% of control levels in males fed 60% and 40% sucrose, resp.; 189% and 165% of control levels in females, resp.). Lipogenesis was reduced to 71, 67, and 73% of the control values in male rats fed the 60, 40, and 20% sucrose diets, resp. (significant at 95% confidence level), and to 69, 65, and 78% of the control values in female rats fed the respective diets (significant at 95% confidence level). Glucose oxidation was also significantly reduced in both males (75, 74, and 82% of controls, resp.) and in females (74, 77, and 90%, resp.). The fructose diet produced a significant increase (143%) in the triglyceride content of the liver in male rats only, and produced significant decreases in lipogenesis and glucose oxidation in males (71% and 74% of controls, resp.) and in females (63% and 77% of controls, resp.). Plotting the amount of dietary sucrose versus the percent increase in liver lipid concentration or triglyceride concentration showed that even a low level of dietary sucrose increased liver total lipids and triglycerides after 26 weeks in males and females. The effect of sucrose on lipogenesis and glucose oxidation from ^{14}C-glucose was nearly at its maximum at 20% of the diet, and no difference was seen in the effect of 40 or 60%. The results indicate that the effect of sucrose could mainly be due to the fructose portion. These studies indicate that the increase in triglyceride levels are comparable with those obtained in rats fed 72% sucrose or fructose diets in previous studies.

7008 INFLUENCE OF EXPERIMENTAL DIETARY CONDITIONS ON HEPATIC ENZYMES OF GLUTAMIC ACID METABOLISM IN RATS. (Eng.) Lal, H.; Agarwal, K. N. (Pediatric Hematology Unit, Banaras Hindu Univ., Varanasi 221005, India.) *Nutr. Metab.* 19(1/2): 20-27; 1975.

Some hepatic enzymes associated with glutamic acid metabolism were studied in rats under various experimental dietary conditions. There was a significant reduction in the levels of all hepatic enzymes measured in rats fed a low protein diet (2% casein) for 8 days; the mean levels of glutamine synthetase, glutamine transferase, glutamic pyruvic transaminase, aspartic α-oxoglutarate transaminase, glutaminase I, glutaminase II, and glutamate decarboxylase were 8.3, 16.4, 84.5, 13.4, 89.0, 33.0, and 8.9 U/g, resp., in the experimental animals, whereas the levels in controls fed a diet containing 15% casein were 9.5, 22.7, 105.8, 21.0, 127.3, 43.2, and 16.5 U/g, resp. When rats fed the low protein diet for 8 days were given a normal diet for the following 8 days, the enzyme levels increased, but were not significantly different from controls. In the animals restored to the normal diet, the activities of glutamic pyruvic transaminase (98.8 U/g), aspartic α-oxoglutarate transaminase (17.3 U/g), glutaminase II (39.0 U/g), and glutamate decarboxylase (14.0 U/g) were significantly increased over those observed in animals on the low protein diet, but were still lower than in controls. In another group of animals, starvation for 7 days resulted in significant decreases in all hepatic enzymes. In animals fed for 8 days on a carbohydrate-free, protein-rich diet containing 90% casein and 5% fat, the levels of all hepatic enzymes were increased; the increases were significant only for glutamine synthetase (12.1 U/g), glutamine transferase (25.2 U/g), glutamic pyruvic transaminase (124.5 U/g), glutaminase I (162.5 U/g), and glutamate decarboxylase (26.2 U/g). In animals fed for 8 days on a low protein diet made isonitrogenous by the addition of urea, the levels of hepatic glutamic pyruvic transaminase, glutaminase I, and glutamate decarboxylase were significantly reduced. When the low protein diet was made isonitrogenous by the addition of ammonium oxalate, the activities of glutamine synthetase, glutamine transferase, pyruvic transaminase, glutaminase I, and glutamate decarboxylase were significantly lowered. When glutamic acid was used as supplementary nitrogen, the levels of glutamine synthetase, glutamine transferase, glutamic pyruvic transaminase, and glutamate decarboxylase were significantly increased. Dietary protein deficiency, due to a decrease in the total pool of free amino acids, may lower the substrate concentration for hepatic enzymes.

7009 EFFECTS OF LOW AND HIGH PROTEIN DIETS ON THE INDUCTION OF MICROSOMAL DRUG-METABOLIZING ENZYMES IN RAT LIVER. (Eng.) Sachan, D. S. (Dept. Pharmacology, Meharry Medical Coll., Nashville, TN 37208). *J. Nutr.* 105(12):1631-1639; 1975.

The effects of low- and high-protein diets on the activity of hepatic microsomal drug-metabolizing enzymes catalyzing oxidation, reduction, and conjugation were investigated in Sprague-Dawley rats. Male and female rats were fed, *ad libitum*, diets containing 3.5% (low protein, LP), 26% (normal protein, NP), and 42% (high protein, HP) casein for 33 days. Five animals from each dietary group were injected i.p. with 10 mg of phenobarbital (PB)/kg on days 30-33. The 10,000 X *g* supernatant and microsomes were prepared from the perfused livers. Both LP and HP diets caused a significant decrease in the activity of biphenyl-4-hydroxylase, an increase in the activity of p-nitrobenzoate reductase, and no changes in the activities of 4-methylumbelliferone glucuronyltransferase or cytochrome P-450. The low doses of PB caused significant induction of cytochrome P-450 ($p<0.10$), biphenyl-4-hydroxylase, and n-nitrobenzoate reductase (except in LP and NP females). The NP and HP males had consistently higher activities of these enzymes than females; however, this sex difference in the first two enzymes was abolished by feeding of the LP diet. It was also found that dietary-protein deficiency retards growth, but excess dietary protein does not provide any significant advantage in terms of weight gain.

7010 TOXIC EFFECTS OF RICIN: STUDIES ON THE PATHOGENESIS OF LIVER LESIONS. (Eng.) Derenzini, M.; Bonetti, E.; Marinozzi, V.; Stirpe, F. (Inst. di Patologia generale, Universita di Bologna, Roma, Italy). *Virchows Arch.* [*Zellpathol.*] 20(1):15-28; 1976.

Protein synthesis and the ultrastructure of the liver and spleen of Wistar rats that received an i.p. or s.c. injection of ricin (1 or 10 μg/100 g) were studied in an effort to clarify the pathogenesis of ricin-induced liver lesions. Although there was no significant change in the mean level of hepatic protein synthesis at 40 hr after the injection of 1 μg of ricin, protein synthesis was reduced to 86% of the control level 22 hr following the injection of 10 μg/100 g of ricin. The rate of protein synthesis in the spleen was reduced to 75% of the control level only 6 hr after this injection, to 25% of the control level after 12 hr, and to 12% of the control level after 22 hr. The rats fed the 1- and 10-μg/100 g doses died from severe focal liver necrosis within 24 and 72 hr after poisoning, resp. The first ultrastructural lesions occurred in the sinusoidal cells, particularly the Kupffer cells. These lesions included vesiculation, fragmentation and degranulation of the rough endoplasmic reticulum, and swelling of the cytoplasm. The lesions in the hepatocytes began only after sinusoidal cells were severely damaged or even necrotic. The 1 μg/100 g dose of ricin produced no detectable light microscopic changes in the spleen at 48 hr after poisoning. After the 10 μg/100 g dose, total necrosis of the reticuloendothelial cells of the red pulp of the spleen was observed. Lymphoid follicles were well preserved, although nuclear debris, together with pyknotic nuclei, occurred in the central portion. Other nuclei appeared vesiculated, and their chromatin was marginated. In animals poisoned with 1 μg/100 g of ricin 24 hr following splenectomy, the sinusoidal cell necrosis was much more extensive. It is postulated that hepatocyte necrosis may be a consequence of the disappearance of sinusoidal cells. This might explain why protein synthesis was relatively unaffected in the liver. Since ricin exerted its toxic effect on the sinusoidal cells, the inhibition was not detectable, these cells being "diluted" by the mass of parenchymal cells.

7011 STUDIES ON IRON TURNOVER IN RATS WITH PORTACAVAL ANASTOMOSIS. (Ger.) Becker, K. (No affiliation given). *Z. Gastroenterol.* 14(Suppl.): 238; 1976.

The effect of portacaval shunt on hepatic iron metabolism is reported. Male Wistar rats received labeled iodine, i.v., in albumin, 1 μCi of ^{59}Fe (II) sulfate by gavage, and ^{51}Cr chromate by injection. Group 1 consisted of rats with portacaval end-to-side anastomosis, group 2 comprised sham-operated rats in pair-feeding studies, and group 3 was the control group on standard diet. The iron content was 95.6 μg/g of body weight in group 1, 47.6 μg/g in group 2, and 73.8 μg/g in group 3. The iron resorption rate was equivalent in all three groups. The RBC ^{51}Cr half-life was 6.6 days in group 1, 13.6 days in group 2, and 10.6 days in group 3; the differences were not significant. The increased iron content of liver with portacaval shunt is neither the result of increased intestinal absorption nor increased hemolysis, but is rather a sequel of the concentration phenomena observed during prominent liver atrophy.

7012 EFFECT OF PORTACAVAL SHUNT ON THE DISPOSITION OF DRUGS WITH AND WITHOUT FIRST-PASS EFFECT. (Eng.) Gugler, R.; Lain, P.; Azarnoff, D. L. (Dept. Medicine, Univ. Bonn, Bonn, W. Germany). *J. Pharmacol. Exp. Ther.* 195(3):416-423; 1975.

The pharmacokinetic parameters of lidocaine, antipyrine, and salicylamide were studied in dogs before and after construction of a portacaval shunt. The drugs were administered p.o. and i.v. on separate occasions, and blood samples were analyzed by chromatography or fluorometry. The systemic availability of lidocaine (10 mg/kg) increased from 14.8 ± 2.8% to 81.3 ± 5.2%, while its elimination rate decreased after portacaval shunting from a $T_{1/2}$ of 74.4 ± 2.3 min to 88.4 ± 3.0 min. The systemic availability of antipyrine (20 mg/kg) was not altered significantly by the surgical procedure (93.0 ± 7.1% before and 102.2 ± 7.1% after). Salicylamide (30 mg/kg) was 21.8 ± 7.8% available in the intact animal; after shunting, it was 57.5 ± 2.5% available. Of the 78% first-pass extraction of salicylamide, 36% was due to hepatic extraction and 42% to intestinal wall extraction. The shunt also reduced the plasma clearance of lidocaine and antipyrine, but not of salicylamide. The apparent distribution volume was decreased only with salicylamide. It is concluded that surgical construction of a portacaval shunt in dogs is a good model to evaluate the first-pass effect. Physicians should lower the dosage of drugs with a first-pass effect in patients with a surgical portacaval shunt or endogenous portal systemic shunts, as seen in liver cirrhosis.

7013 THE EFFECT OF PORTACAVAL TRANSPOSITION ON HEPATIC CHOLESTEROL-7α-HYDROXYLASE ACTIVITY IN THE RAT. (Eng.) Boyd, G. S.; Lawson, M. E. (Dept. Biochemistry, Univ. Edinburgh Medical Sch., Teviot Place, Edinburgh, EH8 9AG, Scotland). *FEBS Lett.* 64(2):435-439; 1976.

The effects of portacaval anastomosis on liver microsomal cholesterol-7α-hydroxylase (ChH) activity and cytochrome P-450 concentration in rat liver microsomes were investigated in 54 male Wistar rats. The rats were killed at fixed periods 10-80 days after the anastomosis, in which an end-to-side technique was used. The postoperative mortality was very low (10%). The liver microsomal ChH activity was significantly elevated in all animals 80 days later. However, the increase was apparent a few days after the operation. The microsomal cytochrome P-450 content was significantly decreased. Animals subjected to anastomosis and subsequently fed a stock diet containing 4% cholestyramine resin, a bile salt sequestering agent, for 5 days, had even higher ChH activities. The results suggest that one of the factors influencing the activity of liver microsomal ChH may be the concentration of bile salts reaching the liver from the blood plasma. Portacaval anastomosis in the rat tended to produce a small decrease in the plasma cholesterol concentration.

7014 ORTHOTOPIC LIVER TRANSPLANTATION AFTER PRESERVATION WITHOUT PERFUSION FOR UP TO SIX HOURS: A CONTROLLED TRIAL EVALUATING DIFFERENT PRESERVATION FLUIDS IN DOGS AND PIGS. (Eng.) Schalm, S. W.; Terpstra, J. L.; Popescu, D. T.; Krom, R. A. F.; Jerusalem, C. (Mayo Clinic, Rochester, MN 55901). *Surgery* 78(5):637-643; 1975.

To investigate the effect of the composition of the preservation fluid on the immediately postoperative transplant function and on subsequent long-term survival, orthotopic liver transplantations were performed in 13 dogs and 12 pigs. Donor and recipient pairs always were litter mates, the dogs being identical according to lymphocyte typing. The ischemic periods were 1, 3, and 6 hr. Four different preservation fluids were used, with marked differences in ionic composition (extracellular versus intracellular) pH, and osmolarity. Within each ischemic period group, the sequence of experiments was randomized with respect to the different preservation fluids. Twenty-four animals survived the transplantation procedure. No differences were found between the preservation fluid groups. Postoperative function of all livers preserved for 6 hr was comparable to those with 1-hr ischemia. Three dogs and four pigs (6 of 7 with livers preserved for 3 or 6 hr) are still alive more than 1 yr after transplantation. The results indicate that consistently excellent liver function leading to long-term survival in 36% of cases can be obtained after liver transplantation with preservation up to 6 hr; for this result, the composition of the preservation fluid is of minor importance.

7015 A NEW MODEL OF EXPERIMENTAL TOXIC HEPATITIS. ACUTE DEGENERATIVE HEPATITIS INDUCED BY FROG VIRUS 3 (FV_3) IN THE MOUSE. (Ger.) Elharrar, M.; Bingen, A.; Drillien, R.; Gendrault, J. L.; Steffan, A.-M.; Kirn, A. (Laboratoire de Virologie, Faculte de Medecine, Universite Louis Pasteur, F-67 000 Strasbourg, France). *Arzneim. Forsch.* 25(10): 1586-1591; 1975.

A new model for hepatocyte necrosis from purely toxic interference in macromolecular synthesis by frog virus, FV_3 is reported. The virus was isolated from renal carcinoma in *Rana pipiens*. FV_3 inoculation, i.p. or i.v., elicits an acute hepatitis in mice, mainly associated with inhibition of RNA synthesis, which is fatal in 24 hr; p.o. or s.c. administration is without effect, even after a lethal dose of 5×10^7 virions. The dose-response curve is "all-or-nothing," and the effect, whose lesions are most prominent in liver, is nonspecific, including modification of chromatin, pyknosis, and nucleolar changes. Cytoplasmic dystrophy and vacuolization, especially of the endoplasmic reticulum, occurs later. Accordingly, nuclear enzymes are chiefly affected and DNA- and RNA-polymerase activity is reduced. Since intracellular virion proliferation does not occur, effective treatment must be directed against the effect of virus protein on host cell metabolism. Mice were given silymarine hemisuccinate (SHS, 30 mg/kg, i.p.), which is equivalent to 208.3 mg silymarine, 20 hr before an LD_{80} injection of FV_3. The mortality was 0%. If SHS was administered 1 hr before the virus, mortality was 20%; administration 3 and 6 hr after virus inoculation resulted in a mortality of 80% in both cases. Against doses double the LD_{100}, single SHS injections led to 75% mortality, whether given 20 or 2 hr before the virus. Two SHS injections (300 mg/kg) 20 or 2 hr before allowed only 35% mortality. The FV_3 LD_{50} for mice is 9 x 10^6 virions; after SHS pretreatment, it rises to 2.5 x 10^7, or 16 million more FV_3 particles. SHS protection is conferred 2 hr after the last SHS injection and increases the survival time. The mean survival in control mice was 24.4 hr and for SHS mice, it was 33-45 hr. The mechanism of SHS prophylaxis of RNA synthesis is not known.

7016 VACCINE AGAINST HUMAN HEPATITIS B. (Eng.) Buynak, E. B.; Roehm, R. R.; Tytell, A. A.; Bertland, A. U., II; Lampson, G. P.; Hilleman, M. R. (Merck Inst. Therapeutic Res., West Point, PA 19486). *JAMA* 235(26):2832-2834; 1976.

A highly purified vaccine was prepared, using hepatitis B surface antigen (HBsAg), and its protective efficacy and safety were evaluated in chimpanzees, guinea pigs, grivet monkeys, and marmosets. The absence of live hepatitis A virus in the vaccine was established by tests in the marmosets. All of 10 guinea pigs, 5 of 6 grivet monkeys, and 5 of 6 chimpanzees given three doses of the vaccine (20 μg, s.c.) developed antibody to HBsAg (anti-HBsAg), the titers being 75, 22.6, and 36.8 in the guinea pigs, monkeys, and chimpanzees, resp. Six chimpanzees given the same dose of vaccine and five unvaccinated control animals were all challenged with approximately 1,000 chimpanzee-infectious doses of live hepatitis B virus, i.v. The control animals, all initially devoid of anti-HBsAg, had hepatitis B infection, as indicated by tests for HBsAg, transaminase elevation, and antibody to hepatitis B core antigen. Five vaccinated animals had anti-HBsAg by the time of challenge. None of the six animals had hepatitis B following challenge. The one animal that did not develop anti-HBsAg on vaccination did develop this antibody following the challenge. The results suggest an eventual role of highly purified viral antigen vaccine for the control of hepatitis B.

7017 CARCINOGEN-INDUCED DNA REPAIR IN PRIMARY RAT LIVER CELL CULTURES; A POSSIBLE SCREEN FOR CHEMICAL CARCINOGENS. (Eng.) Williams, G. M. (Naylor Dana Inst. Disease Prevention, Valhalla, NY 10595). *Cancer Lett.* 1(4):231-235; 1976.

The first determination of damaging action of carcinogens on DNA of primary liver cultures, as measured by unscheduled DNA synthesis representing DNA repair, is reported. Primary Fischer rat liver cell cultures were exposed to the direct acting carcinogen, methyl methanesulfonate (2 x 10^{-3}-6 x 10^{-3} M), and to procarcinogens requiring metabolic activation, aflatoxin B_1 and B_2 (1 x 10^{-7}-1 x 10^{-3} M and 1 x 10^{-5} M, resp.). Methyl methanesulfonate induced light nuclear labeling. The mean counts increased slightly with dose (10-14 grains/nucleus), but for the narrow dose range, the means were not significantly different. These doses produced DNA damage, and the DNA-binding agent, chloroquine (3 x 10^{-4} M) blocked the repair of this damage (0 grains/nucleus). Aflatoxin B_1 induced even greater unscheduled DNA synthesis (4-39 grains/nucleus), which increased as the dose increased. The weakly carcinogenic aflatoxin B_2 induced less unscheduled synthesis (7 grains/nucleus) than aflatoxin B_1, confirming the previous finding that the level of repair correlates with carcinogenic potential. Treatment with all carcinogens resulted in equal unscheduled DNA synthesis in both nuclei of binucleate cells, with a few exceptions in which there was up to a 30% difference. The results suggest that this system may be adapted for screening suspected chemical procarcinogens and for investigating the relation between metabolic activation of procarcinogens and DNA damage, DNA repair, and carcinogenicity.

7018 FACTORS INFLUENCING THE ESTABLISHMENT OF THE NORMAL VALUES OF THE RESPIRATORY ACTIVITIES OF HUMAN LIVER MITOCHONDRIA. (Eng.) 7063 THE ROLE OF THE COLON IN UREA METABOLISM IN MAN. (Eng.) Gibson, J. A.; Park, N. J.; Sladen, G. E.; Dawson, A. M. (St. Bartholomew's Hosp., London E.C.1, England). *Clin. Sci. Mol. Med.* 50(1):51-59; 1976.

To study the role of the colon in urea hydrolysis and ammonia production, urea excretion in 29 ileostomy effluent specimens was determined as an indirect measure of the amount of urea entering the colonic lumen. Urea turnover was determined in six controls and six patients with nonfunctioning colons. The ileostomy urea concentration was 0.58-9.17 mM, and the determination of the blood urea concentration in 26 cases revealed that the mean ratio of ileostomy urea to blood urea was 0.715. In the normal subjects, the mean breakdown of urea in the gut (determined by the plasma disappearance of i.v.-administered ^{14}C-urea) increased from 4.3 mmol/hr on a low protein (40 g) diet to 7.6 mmol/hr on a high protein (100 g) diet ($p<0.02$). This increase in dietary protein intake also resulted in an increase in urea production from a mean value of 14.2 mmol/hr to 28.2 mmol/hr. When urea metabolism was expressed as a percentage of urea synthesis, the percentage was unaffected by variations in dietary protein. When this percentage was compared in the normal subjects and the patients with nonfunctioning colons, the removal of the colon resulted in a fall from a mean value of 28.3% in controls to 19.7% in patients with nonfunctioning colons ($p<0.025$). The results suggest that the colonic lumen is not the only site of intestinal ureolysis and that significant quantities of urea must be broken down either at a juxtamucosal site or in the ileum.

7064 ON THE HYDROPHOBIC PART OF AMINOPEPTIDASE AND MALTASES WHICH BIND THE ENZYME TO THE INTESTINAL BRUSH BORDER MEMBRANE. (Eng.) Maroux, S.; Louvard, D. (Centre de Biochimie et de Biologie Moleculaire du Centre National de la Recherche Scientifique, 31, Chemin Joseph-Aiguier, 13274 Marseille Cedex 2, France). *Biochim. Biophys. Acta* 419(2):189-195; 1976.

Evidence is presented to show that the hydrophobic parts of aminopeptidase and the maltases $M_2 + M_3$ in porcine intestinal brush border membranes are relatively short polypeptide chains rich in apolar residues and containing no disulfide bridges. The detergent and hydrophobic forms of the enzymes were purified. These hydrolases were composed of a hydrophilic, sugar-containing, and enzymatically active part and a smaller hydrophobic part presumably binding the catalytic part to the lipid matrix of the membrane. Hydrophobic parts detached by trypsin from the detergent forms were shown to have molecular weights of 8,000 to 10,000. The aminopeptidase and maltases contained no disulfide bridges but did contain a large number of hydrophobic residues typical of intrinsic membrane proteins. However, their overall amino acid composition was different. The hydrophobic parts appeared to be N-terminal in the detergent forms of the enzymes. It is concluded that the three hydrolases are amphipathic molecules.

7065 CIRCADIAN RHYTHMS IN DIGESTIVE ENZYMES IN THE SMALL INTESTINE OF RATS. I. PATTERNS OF THE RHYTHMS IN VARIOUS REGIONS OF THE SMALL INTESTINE. (Eng.) Saito, M.; Murakami, E.; Nishida, T.; Fujisawa, Y.; Suda, M. (Sch. Medicine, Ehime Univ., Shigenobu, Ehime 791-02, Japan). *J. Biochem. (Tokyo)* 78(3):475-480; 1975.

Circadian variations in the activities of maltase, sucrase, trehalase, leucine aminopeptidase, and alkaline phosphatase were studied in the jejunum and ileum of male Wistar rats. The effect of altered feeding schedules on the circadian rhythms was also studied. The activities of these enzymes were higher in the jejunum than in the ileum, and in the distal ileum no sucrase, trehalase, or alkaline phosphatase activity was detected. When the rats were fed *ad libitum,* all enzyme activities exhibited clear circadian fluctuations in the small intestine, with the highest activities at 0000-0400 hr and lowest at 1200 hr. The amplitudes of the rhythms of dissacharidases and alkaline phosphatase were highest in the proximal jejunum; the rhythmic variation was less marked in the distal jejunum and proximal ileum and was not detected in the distal ileum. Leucine aminopeptidase showed a circadian variation in the ileum, with the same amplitude as in the jejunum. When the rats were fed during the day only (from 0900 hr to 1500 hr) for 2 weeks, the circadian variations shifted about half a day, but the amplitude of the rhythm did not change. The results suggest that the circadian rhythms in the digestive and absorptive functions of the small intestine are closely related to the rhythm of food intake.

7066 EFFECT OF DIET ON DIGESTIVE AND ABSORPTIVE FUNCTIONS OF RAT SMALL INTESTINE. (Eng.) Saito, M.; Suda, M. (Dept. Biochemistry, Sch. Medicine, Ehime Univ., Shigenobu, Ehime 791-02, Japan). *J. Nutr. Sci. Vitaminol. (Tokyo)* 21(4):313-315; 1975.

The effect of diet on the digestive and absorption rates of L-histidine and D-galactose was investigated in the small intestine of male Wistar rats. Rats were fed either a diet with high starch (71%) and low casein (5%) contents (I) or a diet with low starch (15%) and high casein (76%) contents (II) *ad libitum* for 5 days. Maltase, sucrase, and leucine aminopeptidase activities were measured in homogenates of the intestinal mucosa. Diet II decreased the activities of maltase ($p<0.01$) and sucrase ($p<0.02$) and increased that of leucine aminopeptidase ($p<0.005$). The corresponding values (in µmol/min/mg of protein) in diets I and II for maltase were 0.389 and 0.289; for sucrase, 0.043 and 0.022; and for leucine aminopeptidase, 0.028 and 0.049. The absorption rate of L-histidine was higher in rats fed diet II (0.477 µmol/min/mg intestine; $p<0.01$) than in rats fed diet I (0.284 µmol/min/mg). The absorption rate of D-galactose was not significantly different in rats on either diet. Thus, the absorption rate of galactose is not influenced by diet, in contrast to disaccharidase.

7067 EFFECT OF ALCOHOL INGESTION ON THE EPITHELIAL CELL POPULATION IN RAT SMALL INTESTINE (Eng.) Zucoloto, S.; Rossi, M. A. (Dept. Pathology, Medical Sch. Ribeirao Preto, Caixa Postal 301, Ribeirao Preto, S.P., Brazil). *Experientia* 32(5):614-616; 1976.

The effect of prolonged alcohol ingestion on the small intestinal cell population in otherwise well-nourished rats was investigated. Male Wistar rats were allowed to drink only a 32% (weight/volume) ethyl alcohol solution in 25% sucrose in tap water for 12 weeks. Controls were not given alcohol. The percentage of cells in division during a given time interval was determined by the colchicine technique. Alcohol-fed rats gained 23%-28% less weight than the controls. Clinical signs of inebriation were commonly seen among these animals. They consumed 27% of their calories as alcohol, and the calories consumed daily were 10% less than that of the control group. The jejunal and ileal mucosae from the alcoholic rats were thinner than those of the controls, and the intestinal crypts had a decreased epithelial cell count, both in the jejunum ($p<0.1$) and in the ileum ($p<0.05$). Mitosis (prophase plus metaphase) per 100 crypt cells was also significantly decreased in the jejunum ($p<0.005$) and ileum ($p<0.005$). The results support the view that alcohol is directly toxic to the small intestine.

7068 EMBRYONIC CHICK INTESTINE IN ORGAN CULTURE: STIMULATION OF CALCIUM TRANSPORT BY EXOGENOUS VITAMIN D-INDUCED CALCIUM-BINDING PROTEIN. (Eng.) Corradino, R. A.; Fullmer, C. S.; Wasserman, R. H. (Dept. Physical Biology, New York State Coll. Veterinary Medicine, Cornell Univ., Ithaca, NY 14853). *Arch. Biochem. Biophys.* 174(2):738-743; 1976.

The stimulation of Ca transport by exogenous vitamin D-induced Ca-binding protein (CaBP) was investigated in embryonic chick intestine in organ culture. The apparatus used allowed the continuous rotation of everted embryonic duodena at the surface of the culture medium, assuring adequate gaseous exchange and nutrient uptake. After culture, CaBP and ^{45}Ca uptake and transport were measured. When vitamin D$_3$ (26 µM) was added to the medium, CaBP was induced in the duodena, tissue uptake of ^{45}Ca was increased 2.8 times, and transmucosal transport was increased 9.3 times over control values. When highly purified chick intestinal CaBP (2.86 µM) was added, tissue uptake of ^{45}Ca was 1.7 times control and transmucosal transport was increased nearly fivefold. A roller-tube culture technique verified the specificity of stimulation of Ca transport in embryonic chick duodena. Bovine intestinal Ca-binding protein and calsequestrin from rabbit sarcoplasmic reticulum (2.86 mM each) bound Ca with high affinity. Purified chick CaBP again stimulated both tissue uptake and transmucosal transport of ^{45}Ca. A potent metabolite of vitamin D_3, 1,25-dihydroxycholecalciferol (6.5 x 10^{-10} M), induced CaBP synthesis and stimulated Ca transport. It is concluded that the vitamin D-induced CaBP is involved in intestinal Ca transport and may be a Ca-transport protein.

7069 DIAMINE OXYDASE IN RABBIT SMALL INTESTINE: SEPARATION FROM A SOLUBLE MONOAMINE OXIDASE, PROPERTIES AND PATHOPHYSIOLOGICAL SIGNIFICANCE IN INTESTINAL ISCHEMIA. (Eng.) Kusche, J.; Richter, H.; Schmidt, J.; Hesterberg, R.; Friedrich, A.; Lorenz, W. (Chirurgischen Klinik der Universitat, D-3550 Marburg a.d. Lahn, Robert-Koch-Strasse 8, W. Germany). *Agents Actions* 5(5):431-439; 1975.

Because diamine oxidase activity is limited to the gut in rabbits, they were used to study the physiological and pathophysiological function of this enzyme in the gastrointestinal tract. The enzyme was purified 100-fold by gel filtration, separated from soluble monoamine oxidase, and the properties of the two enzymes were determined. Diamine oxidase deaminated putrescine (K_m=1.3 x 10^{-4} M; pH optimum 6.4-6.9) and histamine (K_m=8 x 10^{-5} M; pH optimum 7.5), but not serotonin, and was inhibited by aminoguanidine, but not by pargyline. Soluble monoamine oxidase from rabbit small intestine catabolized serotonin (K_m=1.8 x 10^{-4} M; pH optimum 8.8), but not putrescine and histamine, and was inhibited by pargyline, but not by aminoguanidine. Based on these properties it was postulated that *in vitro* intestinal diamine oxidase could inactivate the vasoactive biogenic amine histamine *in vivo*. The small intestine of rabbits was damaged by experimentally inducing total intestinal ischemia. Treatment with aminoguanidine and ischemia killed the animals three times faster than ischemia alone, which supports the hypothesis that intestinal diamine oxidase plays a protective role against histamine.

7070 DISACCHARIDASES OF RAT INTESTINAL MUCOSA UNDER COMBINED CYTOSTATIC TREATMENT WITH VINCRISTINE SULFATE AND IFOSFAMIDE. (Ger.) Hartwich, G.; Domschke, W.; Matzkies, F. (Med. Klinik mit Poliklinik, Univ. Erlangen-Nurnberg, Erlangen, W. Germany). *Arzneim. Forsch.* 26(3):350-352; 1976.

The combined effect of vincristine sulfate (VS) and ifosfamide [IF, 3-(2-chloroethyl)-2-(2-chloroethylamino)-tetrahydro-2H-1,3,2-oxazaphosphorine-2-oxide] on intestinal disaccharidases was studied. SPF Wistar rats received either single doses of 0.1 mg/kg VS and 100 mg/kg IF, i.p., at 12-hr intervals (test A) or single doses of 0.1 mg/kg VS and double doses of 100 mg/kg IF, i.p., also at 12-hr intervals (test B). The duodenal and jejunal mucosa 13 cm distal to the pylorus was harvested and saccharase (SH), lactase (LT), maltase (MT), and cellobiase (CB) levels determined. Macroscopically, the animals had reduced vitality and food intake within 48 hr. The gut was inflamed and "stuck together" at 36 and 48 hr. Histologically, there was cloudy swelling, and nuclear caryorrhexis or pyknosis of isolated crypt cells, with round cell clustering interstitially. The villi were slightly flattened on days 2-4 but there was no other modification in the villi or brush border. The gut disaccharidases were significantly reduced ($p < 0.01$) after test A. SH was lowest in duodenum at 36 hr and jejunum at 48 hr. MT was lowest in both gut regions at 60 hr. After increasing in the next 48 hr, the levels fell again significantly, but not to the original depression. Recovery began after 7 days. LT and CB were less affected, but they followed the SH-MT pattern and significantly ($p<0.01$). Test B produced the same effect but the decline was more pronounced. The lowest SH and MT levels were reached after 60 hr, the subsequent increase was lower than that for test A, and the second depression at 132 hr was deeper. LT and CB activities were already decreased after 24 hr ($p<0.01$) and were scarcely measurable thereafter. VS or IF given alone reduces intestinal disaccharidase activities in the rat. However, combined administration of both drugs results in a more drastic decrease in enzyme activities. The possibility is suggested that maldigestion of disaccharides in man may occur due to polychemotherapy.

7071 ENZYMES OF ORNITHINE METABOLISM IN ADULT AND DEVELOPING RAT INTESTINE. (Eng.) Herzfeld, A.; Raper, S. M. (Harvard Medical Sch., Boston, MA 02215). *Biochim. Biophys. Acta* 428(3):600-610; 1976.

7072 STUDIES ON THE COMPOSITION OF PHOSPHOLIPIDS IN RAT SMALL INTESTINAL SMOOTH MUSCLE. (Eng.) Yamada, K.; Imura, K.; Taniguchi, M.; Sakagami, T. (Sapporo Medical Coll., South 1, West 17, Sapporo, Hokkaido 060, Japan). *J. Biochem.* 79(4): 809-817; 1976.

7073 GLUCURONIDATION OF PARACETAMOL, MORPHINE AND 1-NAPHTHOL IN THE RAT INTESTINAL LOOP. (Eng.) Josting, D.; Winne, D.; Bock, K. W. (Inst. fur Toxikologie and Institut fur Pharmakologie, 74 Tubingen, W. Germany). *Biochem. Pharmacol.* 25(5): 613-616; 1976.

7074 SELECTIVE VAGOTOMY OF THE CANINE OESOPHAGUS--A MODEL FOR THE TREATMENT OF HIATAL HERNIA.

(Eng.) Edwards, M. H. (Welsh Natl. Sch. Medicine, Univ. Dept. Surgery, Heath Park, Cardiff CF4 4XN, Wales). *Thorax* 31(2):185-189; 1976.

The effects of progressive freeing of the vagus nerve from the esophagus on the development of hiatal hernias as resulting from stimulation of the cervical vagus were investigated in adult mongrel dogs. Vagal stimulation resulted in tetanic contraction of the thoracic esophagus with displacement of the esophagogastric junction into the chest, producing a hiatal hernia. The response was unaffected by hyoscine and abolished by D-tubocurarine, suggesting that only striated muscle was involved. Complete intrathoracic freeing of the vagus from the esophagus resulted in a loss of the displacement response. This loss was observed when either the right or the left vagus had been freed (right 80%, left 97%). After stimulation of the opposite vagus following complete freeing of the ipsilateral vagus, there was a mean loss of 24%, suggesting that unilateral freeing interferes with the neuromuscular connections of the opposite side. Stimulation of both vagi when one was completely freed produced only a 40% displacement loss, indicating that a maximum loss would probably be achieved by freeing both vagi. Progressive freeing in five stages from the hiatus to the first rib resulted in progressive loss of contraction of the esophagus upon stimulation. No significant differences in resting pressures in the esophagus were recorded. In three of the test animals, freeing of the vagi from the esophagus did not affect the lowered heart rate produced by vagal stimulation, but in another three the fall in heart rate was abolished. The bundles of vagi passing through the hiatus appeared grossly normal after freeing in all test animals. It is suggested that a selective esophageal vagotomy above the lung hilum might prove an effective adjunct to orthodox hiatal hernia repair in man.

7075 VEGETATIVE INNERVATION OF THE ESOPHAGUS. II. INTRAGANGLIONIC LAMINAR ENDINGS.

(Eng.) Rodrigo, J.; Hernandez, C. J.; Vidal, M. A.; Pedrosa, J. A. (Instituto Cajal, CSIC, C/Valazquez 144, Madrid 6, Spain). *Acta Anat. (Basel)* 92(1):79-100; 1975.

The morphology of the terminal intraganglionic endings of the vagus nerve in the esophagus was studied in the cat and rhesus monkey by osmium tetrachloride-zinc iodide staining. No morphological differences between the two species were noted. Two types of fiber were found, distinguishable by the different appearance of their terminal portions, the specific end structures that they form around the neuronal bodies, and the different types of apparatus to which they give rise. Some of the fibers form complex terminal and other laminar processes, and others form simpler types of apparatus consisting of fibers with varicose thickenings ending in club- or budlike formations. Details of the morphology are described. The quantitative distribution of the intraganglionic laminar endings in different regions of the esophagus was studied in three cats. The number of ganglia in each portion of the esophagus remained essentially constant in all three cats, but the middle portion contained fewer ganglia (average, 166) than did the upper or lower portions (average, 219-221). The mean percentage of ganglia with intraganglionic laminar endings was 81.5 for the upper portion, 52.7 for the middle portion, and 77.0 for the lower portion. A hypothesis proposing an afferent function is offered, but confirmation must await further investigation.

7076 A MECHANISM FOR THE INDUCTION OF IMMUNOLOGICAL TOLERANCE BY ANTIGEN FEEDING: ANTIGEN-ANTIBODY COMPLEXES.

(Eng.) Andre, C.; Heremans, J. F.; Vaerman, J. P.; Cambiaso, C. L. (Unite de Recherche de Physio-Pathologie Digestive--INSERM U45, Hopital Edouard Herriot, Lyon, France). *J. Exp. Med.* 142(6):1509-1519; 1975.

A splenic immune response with immunoglobulin A (IgA) as the dominant antibody can be induced in mice with a short intragastric immunization course with foreign RBC; this response is followed by a prolonged period of hyporesponsiveness to similarly administered antigen. In the present study, this hyporesponsiveness was found to be also manifested towards antigen given i.p., and that one is dealing with tolerance, not with failure to absorb antigen from the gut. In contrast, mice primed parenterally and then challenged intragastrically, behaved as if they never had any previous contact with the antigen, with a primary-type splenic response of predominant IgA character. This agrees with the previously published conclusion that splenic responses to enterically absorbed antigen reflect colonization of the spleen by cells sensitized locally in the gut wall, a site not readily primed by the parenteral route. Serum from intragastrically immunized mice contained a very active tolerogen. *In vivo*, it was capable of conferring tolerance to nonimmune recipient mice. *In vitro*, it paralyzed the activity of antibody-producing cells. Inhibitory sera had weak antibody activity, restricted to the IgA class, and contained immune complexes reacting with rheumatoid factor but not with the C1q component of rabbit complement. Elimination of these complexes by means of insolubilized rheumatoid factor abolished the tolerogenic effect. The enterically induced tolerogen seems to consist of immune complexes with IgA as the antibody.

7077 IMMUNE REACTION IN THE GASTRIC MUCOSA: PASSIVE MUCOSAL ANAPHYLAXIS AND EXPERIMENTAL ULCER.

(Eng.) Kondo, M.; Kodama, M.; Kawai, K.; Masuda, M. (Dept. Medicine, Kyoto Prefectural Univ. Medicine, Kawaramachi-Hirokoji, Kamigyo-ku, Kyoto, 602 Japan). *Gastroenterol. Jpn.* 10(2):157-161; 1975.

Immune tissue injury in the dog gastric mucosa was investigated using a purified antigen-antibody system. Anti-bovine serum albumin (BSA) serum and normal rabbit serum (control), in 0.1 ml volumes, were injected into the mucosa of six dogs. Two hours later, 10 mg/kg BSA and 30 mg/kg pontamine sky blue 6B (PSB) were injected i.v. as a challenge. Blueing was observed only at the injection site at 30 min and 2 hr, and marked edema accompanied by massive bleeding in the mucosa were seen at 4-12 hr. The reaction was reduced at 24 hr. Blueing was also observed when, with all other procedures remaining the same, BSA (2 g) was given p.o. Histologically, marked cell infiltrations were observed in the mucosa and submucosa after 1 hr, and edema and massive bleeding, with the destruction of mucosal cells, were seen at 4-12 hr. The direct injection of soluble immune complex (0.1 ml) into the gastric mucosa produced an experimental ulcer in which the parietal cells were relatively resistant to the immune tissue damage. However, there were erosion and marked destruction of the mucosa, and numerous cellular infiltrations were seen. Using a purified antigen-antibody system, the passive cutaneous anaphylaxis technique, the authors obtained an immune reaction, "passive mucosal anaphylaxis," which was significant 4-8 hr after the challenge and was accompanied by massive hemorrhage, never seen in passive cutaneous anaphylaxis.

7078 PARIETAL CELL ANTIBODIES. PART II. CYTOTOXIC ACTIVITIES OF PARIETAL CELL ANTIBODIES. (Eng.) Kogawa, K. (Kyoto Natl. Hosp., Fushimi, Kyoto, Japan). *Gastroenterol. Jpn.* 10(1):52-64; 1975.

Cytotoxic activities of parietal cell antibodies (PCA) in normal human parietal cells were investigated, along with histochemical changes in the rat stomach after administration of rabbit anti-rat gastric mucosa (anti-RGM) sera. The PCA produced atrophy, blistering, and swelling in the protoplasm of the cells and karyopyknosis, thickening of the nuclear membrane, and condensation of nucleoli in the nucleus. Aggregation, swelling, and disintegration of the mitochondria plus vacuoles were often noted. The cytotoxic component was immunoglobulin G. Pylorus-ligated albino Wistar rats were injected through the tail vein with either 1.0, 0.5, or 0.1 ml rabbit anti-RGM sera. The sera had no effect on gastric secretion, but a few histochemical changes were demonstrated. However, they were transient and returned to normal within 60 min. Succinic dehydrogenase activities were most affected, decreasing 3 min after injection, followed by a gradual return to normal. Diphosphopyridine nucleotide values were also significantly decreased. Comparison between chronic active gastritis and chronic thyroiditis and the experimental results indicate that these disorders share identical immunologic aspects, and that some immunological mechanism(s) are involved in the pathogenesis of chronic active gastritis.

7079 EFFECTS OF METHYLPREDNISOLONE, GLUCAGON, AND ALLOPURINOL IN THE PROTECTION OF PANCREATICODUODENAL ALLOGRAFTS PERFUSED FOR TWENTY-FOUR HOURS. (Eng.) Tersingi, R.; Najarian, J. S.; Toledo-Pereyra, L. H. (P.O. Box 223, Univ. Minneapolis Hosp., Minneapolis, MN 55455). *Surgery* 78(5):599-607; 1975.

The effects of methylprednisolone, glucagon, and allopurinol as perfusate additives for pancreaticoduodenal segments during 24-hr preservation were studied in 60 dogs. Pancreaticoduodenal segments were removed from donor animals and subjected to hypothermic flushing and 24-hr preservation in modified cryoprecipitated pooled canine plasma. Methylprednisolone (2 g/l perfusate), allopurinol (250 mg/l), glucoagon (10 mg/l), methylprednisolone plus allopurinol, or methylprednisolone plus glucagon were added to the perfusate. The flow rate during perfusion was significantly higher in the segments perfused with methylprednisolone, alone or in combination with other drugs, than that with allopurinol or glucagon alone. During perfusion, the secretion of pancreaticoduodenal juice, amylase, and trypsin was also significantly higher in the groups perfused with methylprednisolone, alone or in combination. After 24 hr of perfusion, all pancreaticoduodenal grafts exhibited a 15-30% weight gain, except those perfused with methylprednisolone and glucagon, which had only a 10-15% weight gain. From the beginning of transplantation, the pancreaticoduodenal grafts perfused with methylprednisolone and glucagon secreted clear mucous pancreaticoduodenal juice, while those perfused with the other drug combinations temporarily secreted serohemorrhagic juice. The mean survival times of the recipient dogs receiving control segments, segments treated with methylprednisolone, allopurinol, glucagon, methylprednisolone plus allopurinol, or methylprednisolone plus glucagon were 15.0, 18.0, 7.5, 13.5, and 22.0 days, resp. The results show that the addition of methylprednisolone to the perfusate prevents the appearance of necrotic changes after transplantation of preserved grafts. The best results were obtained after transplant of segments perfused with methylprednisolone combined with glucagon.

7080 PORCINE PANCREATIC TRANSPLANTATION. I. AUTOTRANSPLANTATION OF DUCT LIGATED SEGMENTS. (Eng.) Kyriakides, G. K.; Arora, V. K.; Lifton, J.; Nuttall, F. Q.; Miller, J. (Veterans Admin. Hosp., Minneapolis, MN 55417). *J. Surg. Res.* 20(5):451-460; 1976.

A method of autotransplantation of duct-ligated pancreatic segments in female pigs is described, and the effect of various postoperative treatments on survival, viability of grafts, morphologic changes, peripancreatic fluid volume, and insulin production by the grafts is reported. Treatment groups were given one of the following: (1) antibiotics and heparin only (controls), (2) Solu-Medrol steroid (500 mg/day, i.m.), (3) irradiation (5,000 R), (4) Solu-Medrol + irradiation, (5) Trasylol (perfusion with 100,000 U in 250 ml, then 100,000 U/day, i.m.), (6) glucagon (1 mg preoperatively, i.v., then 4 mg twice daily, i.m.), and (7) glucagon + steroid. Animals were sacrificed 1-2 weeks later. Of 24 control animals, 19 survived, 14 of 19 had viable grafts, and 12-14 showed severe morphological changes. Of 17 animals in group (2), 15 survived; 13/15 had viable grafts, with 0 of 13 showing severe morphological changes. In groups (3) and (4), four of six survived and three of four had viable grafts in each group; only one in group (3) showed severe morphological changes. In group (5), six of seven survived, three of six with viable grafts, all of which showed severe morphological changes. All five animals in group (6) survived, two with viable grafts, both of which had severe morphological changes. All six animals in group (7) survived with viable grafts and no instances of severe morphological changes. Insulin production was preserved and continued exocrine function resulted in an accumulation of large volumes of a peripancreatic fluid as a result of Solu-Medrol treatment. When glucagon was added, there was a total inhibition of exocrine function and negligible peripancreatic fluid accumulation, but insulin production continued and the grafts appeared morphologically normal. The implications of the use of high-dose steroid therapy and glucagon to prevent acute damage to duct-ligated pancreatic autografts are that major obstacles to the use of this method in allografts can now be removed.

7081 RADIONUCLIDE IMAGING OF INTESTINAL INFARCTION IN DOGS.

(Eng.) Schimmel, D. H.; Moss, A. A.; Hoffer, P. B. (Dept. Radiology, Univ. California Sch. Medicine, San Francisco, CA). *Invest. Radiol.* 11(4):277-281; 1976.

In vitro and *in vivo* radionuclide imaging was used to detect large and small bowel infarcts in 10 mongrel dogs. A no. 5 French polyethylene catheter was placed in the superior mesenteric artery in seven dogs and in the caudal mesenteric artery in three. Infarction was produced by injection of ceramic microspheres into either artery, followed by immediate removal of the catheter. Immediately following injection, 15 mCi of ^{99m}Tc-pyrophosphate was injected i.v. or intra-arterially, and abdominal scintigrams were taken. Four dogs had the radionuclide injected i.v. after embolization of either the large or small bowel. A second dose of the radionuclide was given after 24 hr, and a second imaging was done 26 hr after infarction. The bowel was then removed and scanned *in vitro*. Six dogs were given the radionuclide intra-arterially, and the same procedure was followed. In three dogs, tissue samples were counted by scintillation counter. All 2-hr control abdominal scintigrams were normal. Of the four dogs given i.v. radionuclide, only one showed abnormal uptake. An abnormal segment of colon was found at the site of the positive image, and *in vitro* scanning confirmed the increased uptake of this segment. This dog alone had a positive external scan, but all had a positive *in vitro* image. The presence of infarction in the positive segments was pathologically confirmed. Of the six dogs given the radionuclide intra-arterially, all had positive *in vivo* scans. Laparotomy showed grossly infarcted bowel in the positive areas. All *in vitro* scans showed areas of increased uptake, which were pathologically demonstrated to be infarcted areas. The *in vivo* scintigrams were superior to those of dogs injected i.v. *In vitro* counting in the one dog given the radionuclide i.v. showed a radioactivity ratio (counts/g) for infarcted to uninfarcted small bowel of about 2:1. In the two remaining dogs of the group injected intra-arterially, the ratio was 6:1. One had a small bowel, and the other a colonic infarction. No calcium foci were detected in any histologic sections. The results suggest that ^{99m}Tc-pyrophosphate may be a useful agent for imaging acute, external bowel infarctions; however, additional work is necessary to determine if a correlation exists between its localization and the degree of tissue damage.

7082 DUODENUM-, ILEUM- AND COLON-SPECIFIC ANTIGENS.

(Eng.) Rabin, B. S. (Dept. Pathology, Scaife Hall, Univ. Pittsburgh, Pittsburgh, PA 15261). *Int. Arch. Allergy Appl. Immunol.* 50(2):133-141; 1976.

The presence of duodenum-, ileum-, and colon-specific antigens in germ-free rats was investigated. An antigen extract was prepared from each intestinal section and from the liver. Four rabbits were immunized with each antigen, and the resulting antisera were tested unabsorbed, absorbed with liver, and absorbed with both liver and bowel segment extracts. All antisera produced several precipitation lines with each extract. The presence of organ-specific antigens was evaluated by reacting the liver-absorbed anti-intestine antisera against rabbit and guinea pig intestinal tissue extracts. Three of the nine sera gave precipitation reactions with both guinea pig and rabbit intestine extracts. There was a single precipitation line that showed a reaction of identity with duodenum, ileum, and colon of both species. This common antigen was also found in rat duodenum, ileum, and colon. Absorption of the antisera with rat ileum removed reactivity to all rabbit and guinea pig intestine extracts. The results show that at least one each of duodenum-, ileum-, and colon-specific antigen are present in germ-free rat intestine. In addition, there is an intestine-specific antigen present at all levels of the bowel. The intestine-specific antigens are in the goblet cell mucus. The cytoplasm of the epithelial cells contains antigen that is shared by other tissues.

7083 A NEW SUBSTRATE FOR THE RAPID EVALUATION OF ENTERIC MICROBIAL OVERGROWTH.

(Eng.) Wolgemuth, R. L.; Hanson, K. M.; Zassenhaus, P. H. (Rohm and Haas Res. Lab., Spring House, PA 19477). *Am. J. Dig. Dis.* 21(9):821-826; 1976.

The para-aminobenzoic acid (PABA) conjugate of cholic acid was used as a substrate for the detection of altered bile acid metabolism. Forty male Sprague-Dawley rats were divided into three groups. One group was given a massive, oral broad spectrum antibiotic regimen to clear the digestive tract of microflora, a second group had the bowel surgically disrupted to cause bacterial overgrowth in the upper small intestine, and a third group served as a control. The rats were given the PABA conjugate either p.o. or by intracecal injection. Urine was collected at 2, 6, 9, 12, and 24 hr, and PABA excretion was determined. The hydrolysis of substrate was determined by measuring the release of free PABA from the substrate *in vitro* during incubation with *Clostridium welchii* powder. The incubation showed that bacteria containing cholyl hydrolases do hydrolyze the PABA conjugate. The K_m from the Lineweaver-Burk plot was 3.62 mM, which compares well with the K_m for natural substrates. When Na-PABA was given alone p.o., the largest percentage of the dose appeared in the urine of control rats during the initial 2-hr period (1.19 ± 0.13 mg). When the cecal route was used, over half the total PABA recovery occurred during the first 2 hr (0.80 ± 0.12 mg). The antibiotic regimen did not significantly affect absorption or excretion. The PABA conjugate, in contrast, was apparently not hydrolyzed in the antibiotic-treated rats, and negligible amounts were recovered. Oral administration to normal rats resulted in excretion of significant amounts of PABA only by the 12-hr collection period. Oral administration of the conjugate to rats with bacterial overgrowth resulted in a 250% greater excretion of PABA (1.11 ± 0.15) than that of the controls at the 6-hr collection (0.42 ± 0.05 mg). Since the mortality rate in the rats with bacterial overgrowth exceeded 50% by the third day, cecum injected normal rats were used as a model for this *in vivo* hydrolysis. The PABA tracer was excreted at the early interval, and by 6 hr, these rats excreted 330% as much PABA as the normal rats given the conjugate p.o. The antibiotic-treated rats again excreted negligible amounts of PABA in all cases. The results show that the conjugated PABA is a sensitive substrate for detection of deconjugation of bile salts by bacterial enzymes.

7084 BILE ACID BIOTRANSFORMATION RATES OF SELECTED GRAM-POSITIVE AND GRAM-NEGATIVE INTESTINAL ANAEROBIC BACTERIA. (Eng.) Hylemon, P. B.; Stellwag, E. J. (Dept. Microbiology, Health Sciences Div., Virginia Commonwealth Univ., Richmond, VA 23298). *Biochem. Biophys. Res. Commun.* 69(4): 1088-1094; 1976.

The rates of selected bile acid transformations by growing cultures, cell suspensions, and lysozyme-treated cell suspensions of *Eubacterium aerofaciens* and *Bacteriodes fragilis* are reported. Growing cultures of *B. fragilis* converted 70%-80% cholate to 7-ketodeoxycholate (7-KD) in 24-36 hr, but *E. aerofaciens* cultures converted only about 6%-8% in 72 hr. Lysozyme-treated *B. fragilis* showed a twofold increase in the conversion of cholate to 7-KD. No detectable cholate transformations occurred in cell suspensions of *E. aerofaciens* during 6-hr incubation, but deoxycholate was converted rapidly to 12-ketolithocholate (12-KL) and lysozyme treatment increased the conversion of cholate to 7-KD more than a 100-fold. The rate of conversion of deoxycholate to 12-KL increased only twofold in the same lysozyme-treated cell suspensions. In *B. fragilis*, the total activity of both NAD-dependent 7-α-hydroxysteroid dehydrogenase and bile salt hydrolase (BSH) increased markedly in spheroplast fractions from cells in the stationary growth phase. Both enzymes were detected in the spheroplast lysate and the Triton-soluble washed membrane fractions, but only BSH was found in the spheroplast medium. It is suggested that although the physiological significance of the different locations of bile acid-transforming enzyme is not clear, transformation reactions may occur in or on the bacterial cytoplasmic membrane.

DIAGNOSTIC PROCEDURES

7107 CARCINOEMBRYONIC ANTIGEN (CEA): A PROSPECTIVE CLINICAL TRIAL IN PATIENTS WITH GASTROINTESTINAL CANCER. (Eng.) Kjaer, M.; Fischerman, K. (Dept. Surgical Gastroenterology C, Rigshospitalet, Copenhagen, Denmark). *Scand. J. Gastroenterol.* 11(Suppl. 37):99-106; 1976.

Plasma carcinoembryonic antigen (CEA) was determined in 29 patients with colorectal cancer, in 37 with gastric cancer, and in 100 blood donors. Using 5 ng/ml as the upper limit of normal, 98/100 blood donors had CEA levels in the normal range (the two elevated levels were 5.1 and 5.4 ng/ml) and 79/100 had levels below 2.5 ng/ml. The level corresponded positively with the degree of cigarette smoking among smokers ($p < 0.001$) and was higher than that in nonsmokers. There were elevated CEA levels in 14/29 colorectal cancer patients and 12/37 stomach cancer patients. For the colorectal cancer patients, numbers were too small to allow statistical correlation of the CEA level with clinical stage of disease, but among the stomach cancer patients, those with disseminated disease had statistically higher levels than did patients with localized disease. CEA determination allowed identification of radically resectable colorectal cancer in 9/23 and of radically resectable gastric cancer in 7/27. Five patients with colorectal cancer (but no patient with stomach cancer) fulfilled the requirements for monitoring. After observation for up to 14 months, a definitive correlation between CEA levels and clinical course was demonstrated in 1/26 patients submitted to macroscopically radical surgery for colorectal cancer. In 2/7 patients with gastric cancer, the CEA values were completely misleading. CEA determination is not recommended as a standard parameter for following up cases of gastrointestinal cancer.

7108 GASTROINTESTINAL HEMORRHAGE FROM ADHESION-RELATED MESENTERIC VARICES. (Eng.) Moncure, A. C.; Waltman, A. C.; Vandersalm, T. J.; Linton, R. R.; Levine, F. H.; Abbott, W. M. (Massachusetts General Hosp., Boston, MA 02114). *Ann. Surg.* 183(1):24-29; 1976.

Six cases of gastrointestinal hemorrhage from submucosal intestinal varices in the region of the superior and inferior mesenteric veins are reported. The patients ranged in age from 16 to 71 yr (5 women, 2 men). The patients presented with frank rectal bleeding or tarry stools without hematemesis or recoverable blood from nasogastric aspiration. All had undergone previous intra-abdominal surgery, and all had portal hypertension. The presence of varices was suggested by the venous phase of mesenteric arteriography. At operation, all patients were found to have large venous communications between portal and systemic venous circuits through postoperative adhesions. The point(s) of bleeding was traced to mucosal erosion over large submucosal varices within the bowel, adherent to postoperative scars or adhesions. In the first patient, the distal ileum exhibited extremely dilated veins within its mesentery, extending over the surface of the intestine up into an adhesion, which bound the ileum to the left pelvic wall at the site of a peritoneal incision for a hysterectomy performed 18 yr previously. A 1-foot segment of ileum was resected, the very large vein was doubly ligated, and a standard end-to-end small bowel anastomosis was performed. In the second patient, massively dilated veins in the mesentery of the distal ileum communicated with enormous systemic venous structures throughout the area of an ovarian cystectomy performed 18 yr previously. Distal ileectomy and right colectomy were performed with end-to-end primary anastomosis. In the third patient, a loop of ileum was adherent to a laparotomy incision, made 19 yr previously, with an extremely large dilated mesenteric vein leading from it. Dense adhesions with venous communications extended from this portion of the ileum into the abdominal wall. The involved ileal segment was freed, the dilated mesenteric vein ligated and divided, and the raw surface of ileum turned in with interrupted fine sutures. In the next two patients, the varices were associated with a cholecystojejunostomy site and a laparotomy incision, resp.; the former was treated by a mesocaval shunt procedure, and the latter by severing the vascular adhesions between a jejunal loop and the abdominal wall and constructing a saphenous vein graft between a mesenteric vein and the inferior vena cava. A 2-foot ileal segment was adherent to the abdominal wall at the point of an appendectomy incision in the last patient; resection of the involved bowel was performed with an end-to-side anastomosis, the dilated ileocolic vein was dissected back to the base of the mesentery, and an end-to-side anastomosis was performed between this vein and the right iliac vein. The authors conclude that the best approach to the treatment of this rare site of gastrointestinal hemorrhage is a direct resection of the involved bowel followed by portal-systemic decompression.

7109 UNUSUAL COMPLICATION OF PANCREATITIS IN ANGIOGRAPHIC VISUALIZATION. (Ger.) Chvojka, J. (Rontgenologische Abteilung, Militarkrankenhaus, Pilzen, Czechoslovakia). *Fortschr. Geb. Rontgenstr. Nuklearmed.* 124(2):131-134; 1976.

A case report of an adventitious finding in an angiographic survey of postoperative pancreatitis is presented. A Billroth II gastric resection for duodenal ulcer had been performed on a 20-yr-old man, with onset of pancreatitis 4 days after surgery. Subsequent celiac artery angiography found a suspected subdiaphragmatic abscess. Unexpected findings included a spherical structure in the middle of the splenic artery and increased vascularization in the body and tail of the pancreas. Celiac and superior mesenteric arteriography 5 weeks later found additional cavity-like structures in the pancreatic body and persistent hypervascularization. The same picture was revealed in control angiography 9 and 18 months postoperatively. Through repeated exacerbation of the pancreatitis, which might have been iatrogenic preoperatively, the arteries and veins became fixed to the pancreas by adhesions, eliciting vascular wall inflammations and pseudoaneurysms.

7110 SECRETIN AND EPINEPHRINE COMBINED IN CELIAC ANGIOGRAPHY. (Eng.) Uden, R. (Dept. Diagnostic Radiology, St. Gorans Sjukhus, S-112 81

Stockholm, Sweden). *Acta Radiol.* [*Diagn.*] *(Stockh.)* 17(1):17-40; 1976.

The diagnostic value of the combined effect of secretin and epinephrine in pancreatic angiography was investigated in 39 patients (6 with carcinoma of the pancreas, 2 metastases in the pancreas, 2 metastases behind the pancreas, 9 pancreatitis, and 1 schwannoma in the duodenal wall; 19 having a normal pancreas, but cancer in other sites, with liver metastases in 12). In all cases, an additional angiographic series was performed without the pharmacodynamic substances. A third series was performed in 32 cases, in 23 with secretin alone and in 9 with epinephrine alone. Secretin (90-150 clinical U) was injected through the catheters 1.5-2 min before the injection of contrast medium; 4-6 μg of epinephrine was injected 15-20 sec before the contrast medium. With secretin and epinephrine combined, and often with secretin alone, small veins, such as the choledochal, the common hepatic, and pancreaticoduodenal veins, were demonstrated. If there was any filling of small veins in or around the head of pancreas, these three, at least, should be identified. Secretin plus epinephrine caused a marked contrast of the abnormal veins and capillaries because a larger amount of contrast medium reached the pancreas. Abnormal veins became filled in every case of pancreatic carcinoma. The demonstration of abnormal veins appears to be a better sign of carcinoma than the four classical signs (vessel displacement, artery stenosis, abnormal arteries, and increased contrasting effect of the tumor). The optimum technique for pancreatic angiography is to include one series with secretin alone, to adequately fill the tail of the pancreas and the splenic and portal veins, and one series with secretin and epinephrine combined.

7111 ENDOSCOPIC RETROGRADE INTRAHEPATIC CHOLANGIOGRAPHY IN LIVER DISEASES. (Eng.) Ayoola, E. A.; Vennes, J. A.; Silvis, S. E.; Rohrmann, C. A.; Ansel, H. J. (Dept. Internal Medicine, Veterans Admin. Hosp., 54th St. and 48th Ave. South, Minneapolis, MN 55417). *Gastrointest. Endosc.* 22(3):156-159; 1976.

The radiographic characteristics of the intrahepatic bile duct system were determined in 56 patients who had nearly simultaneous endoscopic retrograde intrahepatic cholangiography (ERIC) and liver biopsy. All patients with cirrhosis (17) showed abnormalities of ERIC: pruning, stenosis, and irregularity. Ductular displacement was seen in about one-third. Only a third of the 12 patients with portal triaditis and/or fibrosis showed any abnormality. Nine of 10 patients with chronic cholangitis had an abnormal ERIC, primarily, dilation of the intrahepatic ducts. The duct configuration was normal in all cases. In two sclerosing cholangitis patients, extrahepatic focal stenosis with intervening sacculations (beading) and pruning were observed. The findings were abnormal in all seven cases of malignant tumors: marked duct displacement (5), giving rise to a mass effect (3), duct dilatation (5), diffuse stenosis (2), and abrupt branch obstruction (2). Two patients with fatty metamorphosis were indistinguishable from normal except for subtle straightening of the ductular branches. A case of chronic active hepatitis and of hemangioma of the liver appeared normal. It is suggested that attempts should be made to fill the biliary system beyond the bifurcation in order to avoid overlooking abnormalities of the intrahepatic ducts.

7112 INDICATIONS, CLINICAL VALUE AND COMPLICATIONS OF ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY. (Eng.) Kessler, R. E.; Falkenstein, D. B.; Clemett, A. R.; Zimmon, D. S. (Manhattan Veterans Admin. Hosp., New York, NY). *Surg. Gynecol. Obstet.* 142(6):865-870; 1976.

The indications, clinical value, and complications of endoscopic retrograde cholangiopancreatography (ERCP) were assessed in a series of 1,089 procedures performed on 938 patients in two hospitals. The procedure was indicated because of cholestasis in 30.0% and 37.3% of the patients in the respective hospitals, pancreatic disease in 22.6% and 16.9%, gallbladder disease in 9.1% and 4.5%, postcholecystectomy syndromes in 9.8% and 21.4%, and abdominal pain in 26.8% and 19.9%; ERCP was indicated in 1.7% in one hospital for the treatment of choledocholithiasis. The endoscopic retrograde pancreatogram of a patient in whom ERCP distinguished technical failures after a distal pancreaticojejunostomy from progression of an underlying pathologic condition of the duct is presented. In a second patient, ERCP was useful in the detection of an occult choledocholithiasis and the identification of anatomic variants of the biliary tree. In several patients, the site and cause of postoperative biliary fistulas were clearly defined. ERCP was successful in diagnosing the disease in 75.2% of all patients. Diagnostic studies were achieved in 4.4% of these patients by virtue of endoscopic findings, and in 45.4% by cannulation of both pancreatic and biliary ducts. In 25.4%, a single duct demonstrated a diagnostic pattern. ERCP failed to be useful in the diagnosis in 24.8% of the patients. There were two deaths among the 938 patients from sepsis after ERCP, when prompt surgical relief of obstruction was not accomplished. It is concluded that ERCP is an invaluable tool for the diagnosis and management of pancreatic and biliary tract diseases.

7113 INTRAVENOUS CHOLEGRAPHY AND DIAPHRAGMATIC MOVEMENTS IN THE DIFFERENTIAL DIAGNOSIS OF ACUTE CHOLECYSTITIS. (Ger.) Kruse, V. (Kong Georgs Vej 26, 9000 Aalborg, Skorranget 4, Denmark). *Fortschr. Roentgenstr.* 122(6):554-557; 1975.

The problem of common duct and gallbladder visibility in differential diagnosis with i.v. cholegraphy (IVC) is examined. The clinical sample included 79 patients with symptoms suggesting cholecystitis. Biligrafin-filling studies were supplemented by tomography in equivocal cases and special attention was directed to the effect of relative right and left diaphragmatic mobility on the bile ducts, should acute cholecystitis involvement of the pleuroperitoneum be present. Group 1 consisted of 55 cholecystectomized patients with histologically confirmed diagnoses, and group 2 comprised 24 nonsurgical cases with uncertain clinical, laboratory, or radiological diagnoses. The IVC excretion pattern for group 1 included visualization of the common duct and gallbladder in 11, common duct visualization only in 34, and visualization of neither in 10. Of the 11 patients with gallbladder-common duct presentations, 5 had chronic cholecystitis and 4 had chronic cholecystitis plus acute pancreatitis. Of the 34 with common duct presentations only, 27 had acute cholecystitis, 3 had chronic cholecystitis with fibrosis, and 2 had acute pancreatitis plus chronic cholecystitis with fibrosis. Among the 10 negative cases were 6 of acute cholecystitis, 1 of chronic cholecystitis plus acute pancreatitis, 1 of chronic cholecystitis with fibrosis, 1 with adenocarcinoma in the transverse colon with liver metastases, and 1 with a liver abscess. The IVC pattern in group 2 included gallbladder and common duct visualization in 12 cases, 3 of which had acute pancreatitis and 4 had inconclusive diagnoses; there was common duct visualization only in 6, each with acute cholecystitis. There was no visualization of either the gallbladder or common duct in 6, 3 of whom had acute cholecystitis. In 11 of the 34 surgical cases with confirmed acute cholecystitis, movement in the right diaphragm was reduced below movement in the left; this occurred in only 1 of the 34 cases where there was no acute cholecystitis (liver abscess, $p < 0.025$). Normal diaphragmatic motility was found in 10 of the 34 cases with acute cholecystitis and 12 of the 34 without. Although gallbladder opacification was absent in a majority of cases of acute cholecystitis, the differential diagnostic value of IVC must depend on supplementation by diaphragmatic mobility and other studies.

7114 HEPATOSPLENOGRAPHY BY INTRAVENOUS INJECTION OF A NEW IODIZED OILY EMULSION.

(Eng.) Laval-Jeantet, M.; Lamarque, J. L.; Dreux, P.; Laval-Jeantet, A. M.; Launay, J. (Hopital Saint-Louis, F-750 10 Paris, France). *Acta Radiol.* [*Diagn.*] *(Stockh.)* 17(1):49-60; 1976.

The results of hepatosplenography with i.v.-injected iodized lipid emulsion (AG 60 99) in 30 subjects are presented. In 12 subjects, AG 60 99 (0.8-1.8 ml/kg) was infused undiluted over an average period of 1 hr. In the remaining subjects, AG 60 99 was diluted in glucose serum (1:5) and infused over approximately 4 hr. Eighteen patients had Hodgkin's disease with possible metastases or other intrahepatic expanding lesions. The correct diagnosis of histologic lesions was established by hepatosplenography in 5 of 6 of these patients, and this procedure correctly established the diagnosis of a normal spleen in 12 of 14 patients. Hepatosplenography allowed determination of the site of the lesion and the thickness and state of the parenchyma surrounding the lesion; it revealed lesions of the dome or posterior surface, which could not be detected by laparoscopy. Side effects were seen in about 50% of the 30 patients. These included transient fever or a feeling of cold during the injection. Respiratory disturbances with dyspnea occurred in five patients with pulmonary abnormalities, and transient allergic reactions occurred in three. Blood samples were taken in 22 cases. Those patients (12) receiving AG 60 99 by injection showed a moderate drop in RBC (<10%). The most significant hematologic effect was a slight decrease in platelet count (10-20%). These effects were minor and transient; however, they contraindicate hepatosplenoportography in patients with coagulation disorders. The examination of serum lipid content in 12 cases demonstrated no abnormality after AG 60 99 injection. Renal elimination of the iodide was rapid (30% within 24 hr), and the contrast medium was seen in the bladder on films exposed the following day. Hepatography using iodized oily emulsions is a clinically valuable procedure, although it should be avoided in patients with liver insufficiency, coagulopathy, cardiac or cerebrovascular lesions, respiratory insufficiency, pulmonary lesions, or recent lymphography.

7115 RADIONUCLIDE LIVER SCANS IN TUMOR DETECTION. CURRENT CONCEPTS.

(Eng.) Spencer, R. P. (Univ. Connecticut Health Center, Farmington, CT 06032). *Cancer* 37(1):475-479; 1976.

Concepts in radionuclide liver scans in tumor detection are discussed in an effort to integrate various approaches to liver scanning and to place them in perspective. Because of the frequency of tumor metastasis to the liver, hepatic evaluation plays a key role in planning therapy. Dynamic radionuclide transit studies depend upon the dual blood supply of the liver (hepatic artery and portal vein) and can be a useful prelude to static imaging, as most intrahepatic tumors have a hepatic arterial blood supply. Since most tumors cannot accumulate a radioactive colloid, static views are usually obtained after the injection of particulates, which are accumulated by the reticuloendothelial system. A gross defect on the radiocolloid scan indicates the presence of an intrahepatic abnormality, but does not identify the nature of the lesion. Although radiocolloids have dominated liver scanning for years, other agents, particularly radiolabeled materials that bind to tumors, may develop into important adjuncts. Several agents that have been studied include ^{67}Ga-citrate, which enters the liver and spleen and has been used to localize internal abscesses, and radionuclide-labeled tumor antibodies. New approaches being investigated include radiolabeled enzyme substrates or inhibitors (iodoaminopterin, which binds to dihydrofolate reductase) and inhibitors of metabolic pathways (depression of gluconeogenesis by ^{131}I-diphenyleneiodonium). There are at least five other uses of liver scans in patients with tumors: searching for new metastatic lesions during therapy, screening for nonmalignant foci (infections) during therapy, estimating intrahepatic tumor growth, estimating the rate of regression of intrahepatic lesions after irradiation or chemotherapy, and allowing the correct placement of biopsy needles or of radiation therapy portals.

7116 RESULTS OF GASTRIC LYMPHOGRAPHY WITH SPECIAL REFERENCE TO GASTRIC CARCINOMA.

(Ger.) Schacht, U.; Junemann, A.; Becker, H. J.;

Huth, F.; Palomba, P. P.; Kremer, K. (Chirurgische Universitatsklinik A, 4000 Dusseldorf 1, Moorenstr. 5, Dusseldorf, W. Germany). *Dtsch. Med. Wochenschr.* 101(19):725-729; 1976.

Experiences with indirect gastric lymphography in patients with gastroduodenal ulceration and gastric carcinoma are described. The clinical sample included 35 cases of gastric carcinoma (23 men and 12 women; average age, 62 yr) and 17 cases of gastroduodenal ulcers. The carcinomas were localized in the antrum in 7 patients, on the lesser curvature in 8, on the greater curvature in 3, on the corpus-antrum boundary of the lesser curvature in 11, and on the boundary of the greater curvature in 2; 4 patients had residual stump carcinomas. Using a fiberglass endoscope, Lipoidol ultra-fluid was injected into 8-10 different sites in the gastric submucosa and readings were attempted at various times up to 72 hr. The flow of the contrast medium into the nodes followed an imaginary line on the long axis of the stomach, whose midpoint was sagitally between the two curvatures. The contrast medium tended to move in the direction of the nodes on the lesser curvature. In the carcinoma cases, the contrast medium required 14-24 hr to reach the second and third order ganglia. There was no visualization in 4 of the 35 patients and visualization was deficient in 3 patients. Among the others, there were 28, 21, and 15 presentations of the first three nodal orders, resp. The findings included 13 true positives, 6 true negatives, 3 false positives, and 2 false negatives. Surgery was performed on 31 patients. Histologically, the resection preparations showed submucosal edema and foreign body reactions (lipophagic granulomas and giant cell formations limited to the submucosa), but the mucosa and muscle layers were intact. In the 17 ulcer patients, visualization of nodal orders 1-3, resp., was achieved 13, 5, and 5 times. Half of the patients had unusually large nodes with loose structure and small droplets of contrast medium deposits; in the remaining ulcer patients, contrast medium either failed completely or the medium was deposited negligibly in generally very small nodes. In 10 healthy subjects, the first three nodal orders were visualized, resp., 10, 7, and 4 times; there were failures or deficient fillings. Lymphography can provide decisive indications for intervention.

7117 TRANSJUGULAR RETROGRADE PORTOGRAPHY. PRELIMINARY COMMUNICATION.

(Ger.) Thelen, M.; Janson, R.; Schulz, D.; Paquet, K. J.; Thurn, P.; Harler, B. (Radiologische Klinik der Universitat Bonn, Abteilung Chirurgie, 5300 Bonn, W. Germany). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 124(6):531-534; 1976.

Retrograde presentation of the portal system and liver parenchyma during transjugular liver diagnosis is described. The test sample included 14 patients with portal hypertension, and 9 with normal pressure. General anesthesia is preferred. The right internal jugular vein is punctured and a catheter is inserted into the right or left hepatic vein and passed under electrocardiograph control. The contrast medium passes through the sinusoids into the portal circulation. Manual injection pressure is sufficient to fill even the central sections of the portal system. On termination of the presentation, the catheter is retracted to the caval section of the hepatic vein, after which the contrast medium empties from the parenchyma, such that no deposits are detectable after 2-3 min. A small amount of extravasation was found at the catheter point. In cirrhosis, contrast medium depots remain for longer periods, due to poor parenchymal perfusion. The tissue injury involved in multiple attempts to find a portal branch in direct methods are avoided by the relatively noninvasive retrograde portography.

7118 OPTIMAL TOMOGRAPHIC TECHNIQUE TO DEMONSTRATE COMMON BILE DUCT STONES. AN IN VITRO STUDY.

(Eng.) Smith, G. R.; Loop, J. W.; Allan, T. N. K. (Dept. Radiology, Univ. Washington, Harborview Medical Center, 325 Ninth Ave., Seattle, WA 98104). *Am. J. Roentgenol.* 126(1):63-69; 1976.

To reevaluate cholangiography as produced by existing tomographic techniques, a phantom was exposed to a beam collimated to 4.5 x 5.2 inches in the following modes: 10 and 40 degrees linear; 6, 10, 20, and 36 degrees circular; 40 degrees transverse ellipsoidal; and 48 degrees hypocycloidal. Qualities of the phantom included dimensions and orientation of the "common bile duct;" iodide concentration of its contents; size, shape, number, position, and radiolucency of artificial common duct stones; thickness of the subject; and interposition of bowel gas. The 6- and 10-degree circular modes were the optimal methods for i.v. cholangiography with tomography within the technical limitations and constraints outlined. The 10-degree mode was superior in the presence of superimposed gas. It is concluded that 10-degree linear tomography is an efficient method for determining the level of the common bile duct, but is not the best one for obtaining image detail. Thin-section unidirectional or pleuridirectional modes were occasionally helpful in delineating fine detail. These had a narrow zone of focus and permitted very limited sampling within the usual zone of interest. These modes were also inefficient in determining duct level and produced less-useful image detail than 10-degree circular tomography for ducts of normal or slightly larger diameters. It is concluded that they are seldom indicated as the primary modality on tomography of the common duct.

7119 ULTRASONIC DIAGNOSIS OF ABDOMINAL ABSCESS.

(Eng.) Doust, B. D.; Doust, V. L. (Medical Coll. Wisconsin, 8700 W. Wisconsin Ave., Milwaukee, WI 53226). *Am. J. Dig. Dis.* 21(7):569-576; 1976.

The ultrasonic diagnosis of abdominal abscess is reviewed. The technique, the ultrasonic properties of different types of abscesses, the differential diagnosis of an abscess, and the relation of ultrasound to other diagnostic modalities are discussed. The frequency of ultrasound most commonly used for abdominal diagnosis is 2.25 million cycles per second. Most ultrasound abdominal studies can be completed in 20 min or less. Fluid collections are echo-free, well-defined structures that conduct sound very well. Intrahepatic abscesses can be demonstrated in conventional longitudinal and transverse scans. The uppermost parts of the right lobe must be examined by a subcostal, angled approach. Failure to demonstrate a hepatic abscess is good evidence that the liver does not contain an abscess larger than 2 or 3 cm in diameter; the newer greyscale scanners may make lesions smaller than 2 cm in diameter regularly demonstrable, but at present, the limit of reliable resolution has not been determined. Right-sided subphrenic abscesses may be purely subphrenic or may have an associated intrahepatic component. Where there is a subphrenic component, the liver is displaced medially from the lateral abdominal wall and downward from the diaphragm by an echo-free zone. Subhepatic abscesses are easily confused with the gallbladder, although the characteristic shape of the gallbladder will usually allow differentiation. The most difficult area of the abdomen in which to diagnose an abscess is the subphrenic area; the best approach is through the left lower ribs posteriorly and obliquely upward through the left kidney and the spleen. Pelvic abscesses can be seen by an oblique suprapubic approach, provided the bladder is distended. The gallbladder, fluid in a distended bowel loop, a urinoma or hematoma, loculated ascites, a pleural effusion, lymphoceles, or a pancreatic pseudocyst may be confused with an abdominal abscess. The presence of fluid lateral to the liver and the widespread nature of the process generally allow distinction of ascites from multiple abscesses. Differentiation from a pleural effusion depends on identification of the diaphragm, best achieved by longitudinal scans in the decubitus or upright positions. Overall, ultrasonic examination provides the best currently available means of identifying, localizing, and following the progress of intraabdominal fluid collections; reported accuracy is probably in excess of 90%.

GASTROINTESTINAL DISEASES

ESOPHAGUS

7168 A SIMPLE OPEN-END-TUBE METHOD FOR THE STUDY OF OESOPHAGEAL MOTOR FUNCTIONS.

(Eng.) Ismail, A. A.; Shalaby, E. S.; Gaafar, M. A.; Hafez, S. I. (Dept. Medicine, Cairo Univ., Cairo, Egypt). *J. Egypt. Med. Assoc.* 57(1/2):1-8; 1974.

A simplified open-end tube apparatus for studying esophageal motor function was constructed. The apparatus consisted of three flexible rubber tubes (internal diameter, 1.5 mm) fastened together, with terminal openings 5 cm from each other, allowing simultaneous pressure registration. Three water manometers (length, 40 cm; internal diameter, 0.2 cm), each with a long tube and water reservoir, were connected to the esophageal tube at one end and to a mechanical recording system at the other. This system eliminates the need for an expensive transducer, without significantly lowering the accuracy of the method. It has a low sensitivity to rapid oscillations, which eliminates calibration errors, can be built easily, and does not expose the patient to radiation. This method may be useful as a confirmatory or diagnostic tool.

7169 AN UNCONTROLLED COMPARISON OF TREATMENTS FOR ACHALASIA.

(Eng.) Yon, J.; Christensen, J. (Univ. Iowa Hosps., Iowa City, IA 52242). *Ann. Surg.* 182(6):672-676; 1975.

The results of treatment were analyzed in 78 patients with achalasia who received one or more of five different treatment regimens. Six of the seven patients treated with anticholinergics (and occasionally with a tranquilizer) failed to improve; the one patient who improved was asymptomatic for 1 yr and was then lost to follow-up. Among 23 patients treated by dilatation with mercury-filled bougies (usually to a 60 French), 14 experienced some relief of symptoms, but in no case for longer than 4 months. Two patients suffered esophageal perforation, but both recovered with conservative treatment. Ten patients were instructed in periodic self-dilatation by the mercury-filled bougies; of the seven patients that were followed up, all experienced improvement for a few days to a few weeks following each dilatation. All patients who were followed up have required repeated dilatations or the use of a different mode of therapy to alleviate symptoms. Forty-eight patients were treated with pneumatic bag dilatation (usually inflated to 10-13 lb/in^2 for 2 min), and 43 were followed up. Of these, 19 became asymptomatic for a year or more following the initial dilatation. Two of the 19 patients subsequently developed a recurrence of symptoms. Eleven other patients became asymptomatic after pneumatic dilatation, but did not return for yearly follow-up (2 patients) or developed recurrent symptoms within a year (9 patients). Six of the 48 experienced some improvement after pneumatic bag dilatation, but nine were unchanged. No patient developed esophageal perforation after this procedure, but aspiration pneumonia occurred in two. Three patients developed gastroesophageal reflux 3 months to 6 yr after dilatation. Twenty-four patients were treated by esophagocardiomyotomy, 11 of whom had at least one previous pneumatic dilatation. Of the 20 patients followed for a year or more after operation, 17 were asymptomatic. Two of the 17 became symptomatic again 1.5 and 3 yr after the procedure. Three patients were moderately improved postoperatively. Five of the 20 patients followed up developed gastroesophageal reflux. It appears that the only treatments that are clearly beneficial to patients with achalasia are pneumatic dilatation and esophagocardiomyotomy.

7170 MORTALITY IN OESOPHAGEAL ATRESIA.

(Eng.) Cozzi, F.; Wilkinson, A. W. (Children's Hosp., Univ. Rome, Rome, Italy). *J. R. Coll. Surg. Edinb.* 20(4):236-243; 1975.

The mortality rates, treatment, and incidence of associated anomalies of esophageal atresia were compared in 60 neonates treated between 1967 and 1973 and in 93 other neonates treated between 1959 and 1967. The mortality rate during the first admission in the newer series was 28%, and that in the earlier series was 35%; the overall death rates were 33% and 43%, resp. Of 32 neonates with esophageal atresia combined with lower pouch fistula in the earlier series, a primary anastomosis was made in 13; 5 of these patients died. In the remaining 19 infants, the treatment was divided in stages in an effort to reduce the mortality. However, 14 of these patients died. In the more recent series, the operation was done in stages only if the gap between the two pouches was too wide for a primary anastomosis to be made. There were 52 patients with esophageal atresia combined with lower pouch fistula in the later series, and 14 underwent the operation divided into stages; 6 of these infants died. Three of the 52 patients died before an operation could be attempted, and the remaining 35 patients underwent primary anastomosis; 8 of them died. In nine patients with a wide gap between the pouches, attempts to lengthen the proximal pouch were made by stretching with a bougie. In five of these patients, the delayed anastomosis broke down, and a colon replacement was necessary. The incidence of severe associated anomalies in the group treated between 1967 and 1973 was 28%, while that in the earlier group was 32%. In the combined series, esophageal atresia was associated with an anorectal anomaly in 28; 14 of these patients had other associated anomalies, and 12 of them died. Twenty-seven patients with esophageal atresia also had severe anomalies of the heart and great vessels, and 23 of them died. The authors conclude that when a primary anastomosis is not feasible because of the wide gap between the pieces of esophagus, immediate cervical esophagostomy and gastrostomy, followed by bridging of the gap with a colon segment at 1 yr of age, is the treatment of choice.

7171 LONG-TERM RESULTS AFTER SURGERY FOR ESOPHAGEAL ATRESIA.

(Ger.) Koch, A.; Ellers, J.; Krtsch, H.; Siewert, R. (Klinik Allgemeinchirurgie, Univ. Gottingen, Gottingen, W. Germany). *Z. Kinderchir.* 18(1):33-44; 1976.

The results of long-term follow-up of successful surgery for neonatal esophageal atresia are reported. The sample consisted of 27 cases; the longest postoperative follow-up term was 23 yr, and the shortest was 16 yr. Three patients reported a frequency of upper respiratory tract infections of more than five times/yr. Occasionally painful deglutition in excess of four episodes/yr was admitted by eight of the patients; all others noticed a decrease in problems after age 7. The physical development of the subjects followed a normal age-compatible distribution curve, except for five girls and two boys below the 50th percentile in weight, of whom four were also below the 50th percentile in height. Thoracic asymmetry was present in 12 of the 27 patients. There was positive insulin stimulation in 21 cases, with a basal gastric acid secretion of 3 mEq/hr rising to 13 mEq/hr. Endoscopy revealed no esophageal stenosis; esophagitis or endobrachy esophagus in 1 of 23 patients was of no clinical importance. Radiologically there was prominent scoliosis in 2 cases, lower cervical and upper thoracic spinal anomalies in 2 cases, rib deformities in 22 cases, and pleural fixation in 4, but no lung parenchymal changes in any. One esophageal stenosis was found radiologically; a blind paraesophageal fistula secondary to anastomotic insufficiency 23 yr earlier. Slight indentations at the anastomosis level occurred in 21 cases, and the yo-yo phenomenon in 24. There was no hiatal hernia or esophageal reflux. Esophageal manometry found an average 9-cm long hypomotile segment, but primary peristalsis was present to some extent in all patients. The average lower esophageal sphincter pressure was 18.6 mm Hg in the patient group, compared to 19.4 mm Hg in the control group, indicating that the cardiac sphincter mechanism improves with aging.

7172 GASTRO-OESOPHAGEAL REFLUX DISEASE: CORRELATION OF SUBJECTIVE SYMPTOMS WITH 7 OBJECTIVE OESOPHAGEAL FUNCTION TESTS.

(Eng.) Krejs, G. J.; Seefeld, U.; Brandli, H. H.; Bron, B. A.; Caro, G.; Schmid, P.; Blum, A. L. (Dept. Medicine, Stadtspital Triemli, Birmensdorfer Str. 497, CH-8063, Zurich, Switzerland). *Acta Hepatogastroenterol. (Stuttg.)* 23(2):130-140; 1976.

Seven tests for the diagnosis of gastroesophageal reflux were administered to 24 healthy controls and to 48 patients with symptoms of reflux disease. The patients had no concurrent gastrointestinal disease, had not had gastric or duodenal ulcer within 5 yr, had no esophageal stenosis, and had no previous gastrointestinal surgery. The correlation coefficient between subjective symptoms and test results was best with acid clearance from the distal esophagus ($r=0.558$, $p<0.001$). Other tests in decreasing order of correlation were: suction biopsy 5 cm above the lower esophageal sphincter with evaluation of granulocytic infiltrates ($r=0.450$, $p<0.001$), radiologic demonstration of hiatal hernia ($r=0.435$, $p<0.001$), reflux provocation test ($r=0.359$, $p<0.01$), modified Bernstein test ($r=0.322$, $p<0.01$), acid reflux test ($r=0.252$, $p<0.05$), and resting pressure of the lower esophageal sphincter ($r=0.246$, $p<0.05$). The Maudsley Personality Inventory did not correlate with the subjective symptoms ($r=0.188$, $p>0.1$). Stepwise multiple regression analysis revealed that the most useful combination of tests was acid clearance + modified Bernstein test + histological examination of suction biopsies + radiology. Addition of any other test did not result in any further information. It is concluded that single tests cannot distinguish clearly between normal and abnormal reflux, but a combination of tests more nearly approaches this goal.

7173 FUNDOPLICATION FOR REFLUX ESOPHAGITIS: MISADVENTURES WITH THE OPERATION OF CHOICE.

(Eng.) Polk, H. C., Jr. (Dept. Surgery, Univ. Louisville Sch. Medicine, Health Sciences Center, Louisville, KY 40201). *Ann. Surg.* 183(6):645-652; 1976.

Complications associated with a series of 312 fundoplication operations performed for the control of reflux esophagitis are discussed. A transabdominal approach was employed in 220 cases, and 92 were approached through the thorax. Intractable esophagitis was the indication for surgery in 92%. At a mean follow-up of 3.8 yr, the failure rate was 4.1%, half due to primary anatomic recurrence of hernia and half to recurrence of reflux esophagitis. Incidental splenectomy was required in 7% because of unintentional injury to the spleen. Operative wound infection occurred irregularly and was more frequent among patients undergoing abdominal operations. The use of 2-0 silk rather than 3-0 silk for the sutures eliminated dehiscence of the fundoplication. The most frequent nuisance complication was transient dysphagia, typically appearing on the 10th postoperative day and disappearing by the 20th day. Each of the 58 patients who developed this problem responded immediately when a liquid diet was maintained for 2 weeks. Major problems were associated only with unintentional injury to the spleen, mobilization of an acutely inflamed esophagus, and other visceral injury. In none of four patients requiring excision of a fibrotic Schatzki ring was difficulty encountered when the excision was approached by high gastrotomy. Three patients died during hospitalization, one from fulminant gram-negative pneumonitis, one from uncontrolled sepsis, and one from a myocardial infarction. Six per cent of patients complained of symptoms consistent with the "gas bloat" syndrome; they disappeared within 3 months in all but one patient. Overall morbidity in the last 100 patients of the series declined from 14% to 5%, and no deaths have occurred in the last 158 persons undergoing fundoplication operations.

7174 ESOPHAGEAL FUNCTION IN PROGRESSIVE SYSTEMIC SCLEROSIS.

(Eng.) Krejs, G. J.; Lobsiger, M. M.; Rau, R.; Bron, B. A.; von Buren, U. S.; Peter, P.; Brandli, H. H.; Pirozynski, W.; Blum, A. L. (Dept. Medicine, Stadtspital Triemli, Birmensdorfer Str. 497. CH-8063 Zurich, Switzerland). *Acta Hepatogastroenterol. (Stuttg.)* 23(1):40-46; 1976.

Esophageal function was studied in 13 consecutive patients with systemic progressive sclerosis (PSS) by acid-clearance measurements in the distal esophagus, suction biopsy of the distal esophagus, three-point manometry, cineradiography, and provocation of gastroesophageal reflux. Esophageal symptoms were reported in eight patients: dysphagia (7), retrosternal burning (5), pharyngeal burning (5), pain or swallowing (2), and one case each of retrosternal pain, retrosternal tightness, and vomiting. Only one of four patients with PSS of less than 2 yr duration had esophageal symptoms, but they were present in seven of nine of those with the disease for more than 2 yr. Subjective symptoms could not be predicted clearly on the basis of test results. Absence of peristalsis, the retention of air, and dilatation were noted with cineradiography and three-point manometry. Relaxation of the lower esophageal sphincter (LES) was normal in seven of eight; in one, it could not be measured because of a resting pressure of 0. With normal primary peristalsis and normal LES resting pressure, acid clearance was normal or only slightly abnormal. Acid clearance became progressively more prolonged with more severe derangement of peristalsis or LES pressure, and when both were destroyed, acid clearance was impossible. Acid clearance could not differentiate between the pathology of the esophageal body and that of the LES. The muscularis mucosa or blood vessels obtained by suction biopsy did not show any changes diagnostic of PSS. Absence of peristalsis occurred as early as 1 yr after diagnosis of PSS and as late as 5 yr. Impairment of pressure was related linearly to duration of the disease ($p<0.05$). The reflux-provocation test directly demonstrated a pathological reflux in 9/13, but in only 4 of these was a pathological reflux also demonstrated by cineradiography, indicating the limited value of radiology here. It is concluded that extensive esophageal damage may be present in PSS in the absence of esophageal symptoms.

7175 PEPTIC ESOPHAGITIS AND TUMOR-CALCIFICATION IN THE ZOLLINGER-ELLISON SYNDROME. (Ger.) Rosenbusch, G.; Lamers, C.; van Tongeren, J. (Roentgendiagnostische Abt., Innere Klinik der Universitat Nijmegen, Sint Radboud Ziekenhuis, Netherlands). *Radiologe* 15(5):210-214; 1975.

The relation between acute stenosis in the distal esophagus and Zollinger-Ellison syndrome (ZES) is examined. The clinical sample consisted of 10 ZES patients with acute stenosis diagnosed from episodes of reflux esophagitis. One 26-yr-old man had been treated six times for recurrent gastric or duodenal ulcer, both surgically and conservatively. A gastric stenosis of the distal esophagus and two large infiltrating ulcers at the level of the Billroth II anastomosis were confirmed radiologically. The ZES diagnosis was also based on hypergastrinemia and greatly elevated gastric acid secretion (168 mEq/hr/12 hr). A total gastric and distal esophageal resection and esophagojejunostomy were performed. There was no peroperative or angiographic evidence of pancreatic tumor. The stenosis was iatrogenic, consequent to mechanical changes after multiple gastric operations. Calcification of a gastrin-secreting pancreatic islet tumor was found in a 34-yr-old man with a history of recurrent duodenal ulcers and concurrent hyperparathyroidism. After parathyroidectomy and removal of a renal pelvic stone, the plasma calcium and gastric problems were reduced for 9 yr. Subsequent radiology on renewal of gastric pain revealed a gastric ulcer and calcification in the pancreatic body. ZES was diagnosed on the basis of hyperacidity. Total gastric resection with excision of a large pancreatic tumor and nodal metastases were performed. Histology revealed a non-beta cell tumor with calcification in the parenchyma, hyaline connective tissue, and necrotic foci. Calcification in the tumor was sometimes luminal, surrounded by columnar cells. The serum gastrin was 1,495 pg/ml, 3 yr postgastrectomy. Changes of the stomach and the small intestine due to gastrin-producing tumors are important diagnostic signs for ZES. However, peptic esophagitis and calcification of the gastrin-producing pancreatic tumor are atypical for ZES.

STOMACH

7186 SCANNING ELECTRON MICROSCOPY OF GASTROSCOPIC BIOPSIES. (Eng.) Fallah, E.; Schuman, B. M.; Watson, J. H. L.; Goodwin, J. (Div. Gastroenterology, Henry Ford Hosp., Detroit, MI). *Gastrointest. Endosc.* 22(3):137-144; 1976.

Specimens obtained from the gastric mucosa of four patients with normal stomachs, three with erosive gastritis, and three with chronic nonspecific gastritis were compared by scanning electron microscopy (SEM), to gain information on mucosal alterations to injury. The biopsy specimens were fixed immediately, without pretreatment, and were subjected to critical point drying. In the normal stomach, the openings to the gastric pits were round or oval and were located relatively uniformly over the surface (1 pit/ 3,500 μ^2). In erosive gastritis, the pits were increased in number (1/2,300 μ^2), and in chronic nonspecific gastritis, they were decreased (1/23,000 μ^2). The ostia of the gastric pits in the latter condition were huge and varied in shape. In the normal mucosa, the cells gave a cobblestone appearance, and micropits were dispersed over the surface. A cobbletone appearance was more prominent in erosive gastritis, and the cells contained few, if any, micropits. The epithelial cells of the normal stomach were found to contain unique bulb-like structures that were concentrated toward the margins of the cells. These projections were connected laterally by short necks, which ran parallel to the cell surface in different directions. In erosive gastritis, the bulbous projections were smaller in diameter and somewhat sparser; they were distributed evenly over the cell surfaces, rather than concentrating at the margins. The connecting necks were smaller than in the normal stomach. In nonspecific gastritis, the bulbous projections resembled true microvilli and were evenly distributed over the cell surfaces. The method of specimen preparation plus the higher resolution of the SEM may account for the first known observation of the bulb-like projections in this study. It is postulated that in the normal stomach the interconnecting necks form a web of knotted strands that contributes to mucosal resistance.

7187 THE ROLE OF BETA-ADRENERGIC STIMULATION IN HUMAN GASTRIC SECRETION. (Ger.) Mertz, D. P.; Papavassiliov, K. (Kurklinik am Park, Postfach 2340, 4934 Horn-Bad Meinberg 2, W. Germany). *Med. Klin.* 71(23):987-991; 1976.

The effect of two beta-receptor stimuli on acid and electrolyte secretion in the stimulated and nonstimulated human stomach is analyzed. Oxyfedrin (OX) was administered at a dose of 8 mg, i.v., to nine women and five men, all of whom were between 21-50 yr of age and five of whom had either chronic gastritis or duodenitis. Isoproterenol (IS) was given twice at doses of 1 mg or 2.5 mg, i.m., at 15-min intervals to two women (20-39 yr of age) and six men (23-44 yr of age), two of whom had chronic gastritis and duodenal ulcer. Gastric stimulation after secretory baseline determination was induced by 1.2 μg/kg pentagastrin (PG) in i.v. infusion for various 15-min periods. OX had no effect on volume rate or concentration and secretion rate of hydrogen ions (H), chloride ions (Cl), sodium ions (Na), potassium ions, calcium ions, or magnesium ions (Mg) without PG. With PG, the increases were in volume rate from 1.33 to 3.17 ml/min, H secretion from 44 to 107 mEq/l, H secretion rate from 56 to 336 mEq/min, Cl secretion from 95 to 136 mEq/l, and Cl secretion rate from 123 to 429 μEq/min. Sodium secretion, but not secretion rate, declined from 44 to 18 mEq/l. The modifications were significant at p=0.001, except for Na at p= 0.05. Ca also decreased after PG, from 1.3 to 0.3 mEq/l. With OX administered during maximal PG stimulation, the Mg secretory rate and secretion fell from 2.4 to 0.2 μEq/min (p=0.001) and from 0.79 to 0.07 mEq/l (p=0.05). H secretion and Cl secretory rate rose, resp., from 82 to 99 mEq/l (p=0.05) and 354 to 499 μEq/min (p=0.05), while Na secretion fell from 30 to 19 mEq/l (p=0.05). IS had no effect on basal or maximal PG stimulation. Only after PG challenge was the H and Cl excretion raised, resp., from 29 to 76 and from 76 to 117 mEq/l (p= 0.01). Since IS is without effect on gastric juice formation, the beta-receptor stimulation by OX is not responsible for the potentiation of H-ion secretion during increases in its concentration.

7188 GASTRIC XANTHOMA. (Eng.) Mast, A.; Elewaut, A.; Mortier, G.; Quatacker, J.; Defloor, E.; Roels, H.; Barbier, F. (Akademisch Ziekenhuis, De Pintelaan 135, B-9000 Ghent, Belgium). *Am. J. Gastroenterol.* 65(4):311-317; 1976.

Seven cases of gastric xanthoma (GX) are presented. Gastroscopy was performed, and serum lipid levels were determined in each patient; in one, a biopsy specimen of the GX was examined by electron microscopy. The patients (6 men and 1 woman) ranged in age from 54 to 70 yr. The predominant presenting symptoms were epigastric pain and, in some cases, weight loss. In patient 1, gastroscopy revealed a small hiatal hernia and four GX were seen on the vertical part of the lesser curvature, 1-5 mm in size. An ulcer of the vertical part of the lesser curvature was detected in patient 2, 1 yr prior to the detection of four GX on the larger curvature of the antrum; the GX ranged from 1 mm to 1 cm in size. Patient 3 had undergone Billroth II gastrectomy 18 yr prior to the detection of several GX in the gastric remnant and in the mucosal folds of the efferent loop. Signs of stomatitis and abundant bile reflux were noted. An ulcer of the lesser curvature was observed in patient 4; 6 weeks later, the ulcer was not observed, but a 1-cm wide, slightly elevated GX was seen on the anterior wall of the corpus. A small hiatal hernia was also seen. Patient 5 was found to have a prepyloric ulcer on the lesser curvature; 6 weeks later, the ulcer had healed, but a GX (5 mm in diameter) was found in the same area. Six GX, abundant bile reflux, gastritis, and intestinal metaplasia were found postoperatively following a Billroth II gastrectomy in the sixth patient. The seventh patient had a 4-mm wide GX on the larger curvature. Histologically, clusters of foam cells were seen in the lamina propria in all cases. Intestinal metaplasia occurred in all patients and gastritis in six patients. In patient 3, groups of foam cells in the jejunal GX were also seen in the submucosa. In patient 7, electron microscopy revealed irregular nuclei, well-deveoped Golgi apparatus, dilated rough endoplasmic reticulum saccules, and electron-dense cytoplasm containing fibrils. There were three types of vacuoles in the phagocyte cytoplasm: clear, osmiophilic, and those containing reticulated material. In patients 1 and 7, repeat endoscopy after 6 and 2 months, resp., showed that GX had disappeared. In patient 2, the GX had decreased in size after 6 months. In patient 3, the lesion was unchanged after 3 months. Slight hypertriglyceridemia (194-234 mg/100 ml) occurred in four patients; however, there was no correlation between GX and hypercholesterolemia.

7233 A CELLULAR-BIOCHEMICAL EVALUATION OF GASTRIC BODY MUCOSA AND MUSCULAR LAYER IN PATIENTS WITH DIFFERENT BASAL ACID OUTPUTS. (Eng.) Mozsik, G.; Vizi, F.; Kutas, J. (Univ. Medical Sch., H-7643 PECS, Hungary). *Scand. J. Gastroenterol.* 11(2):205-211; 1976.

The gastric corpus mucosa and muscular layer of patients with decreased, normal, and increased basal acid output (BAO) levels (<2.0 mEq/hr, 2.0-4.0 mEq/hr, and >4.0 mEq/hr, resp.) were analyzed biochemically. As the BAO increased, the levels of NA$^+$-K$^+$-dependent ATPase activity, tissue adenine-adenosine, AMP, ADP, ATP, phospholipid phosphates, and RNA all increased significantly in the gastric corpus mucosa. No significant changes in these parameters occurred in the gastric body muscular layer of any of the patients. It is concluded that the energy required for acid secretion is derived from the transformation of ATP into ADP and that the biochemical nature of the cells of the human gastric mucosa, but not in the muscular layer, is altered by changes in BAO.

SMALL INTESTINE

7263 GROWTH AND FAT ABSORPTION AFTER RESECTION OF ILEUM IN CHILDHOOD. (Eng.) Valman, H. B. (Northwick Park Hosp. Clinical Res. Center, Harrow, Middlesex, England). *J. Pediatr.* 88(1):41-45; 1976.

An assessment of height and weight of 12 children who survived resection of over 45 cm of ileum 3-16 yr previously was made and compared with siblings and parents. One year after the resection, all 12 patients were able to take a normal diet without consequent diarrhea. The weights of the children were found to be appropriate for their heights. Subcutaneous fat thickness percentiles were similar to weight percentiles in all patients. The patients tended to be shorter than their siblings, but only two children were below the third percentile, compared with parental heights. Vitamin B_{12}

absorption ranged between 0 and 77%, confirming the marked impairment of ileal function in the majority of these patients. Fat excretion was not decreased by p.o. antibiotics in the two patients tested (9.1-9.3 g/day and 14.1-14.6 g/day). The serum levels of vitamins A, D, and E were normal, although steatorrhea (without diarrhea) was still present in the older children. The results suggest that some children may tolerate a normal diet and grow well despite persisting defects in absorption following extensive ileal resection.

7264 CONTROL OF DUODENAL HAEMORRHAGE WITH CYANOACRYLATE. (Eng.) Goldin, A. R. (Groote Shuur Hosp., Observatory 7925, Cape Town, South Africa). *Br. J. Radiol.* 49(583):583-588; 1976.

The cases of three patients in whom massive duodenal bleeding was successfully treated by the selective intra-arterial injection of Isobutyl 2 cyanoacrylate are presented. The first patient, a 53-yr-old man who had undergone left nephrectomy for renal carcinoma with irresectable aortic nodes, developed massive bleeding from an acute ulcer of the second part of the duodenum. The bleeding persisted despite vagotomy, pyloroplasty, gastrostomy, Polya's operation, and pitressin infusion. Cyanoacrylate ($0.2\ cm^3$) was injected into the posterior superior pancreatoduodenal artery via a coaxial catheter passed through a Cordis catheter. This completely occluded the gastroduodenal artery and glued the coaxial catheter to the vessel occluding the catheter lumen. Following removal of the coaxial catheter, celiac arteriography demonstrated complete occlusion of the gastroduodenal artery with no extravasation. Repeat inferior pancreatoduodenal arteriography demonstrated persisting extravasation, and cyanoacrylate ($0.2\ cm^3$) was injected to occlude this vessel; the extravasation was controlled, and the anterior superior pancreatoduodenal artery was filled via collaterals. During a 9-month follow-up, there were no further episodes of gastrointestinal bleeding. The second patient, a 70-yr-old woman, experienced melena on the 12th day following an anterior resection for rectosigmoid carcinoma. An acute duodenal ulcer was found, and the bleeding persisted despite pitressin infusion. The bleeding was controlled by cyanoacrylate (two divided doses of $0.1\ cm^3$, sandwiched between saline) into the gastroduodenal artery. No bleeding occurred during a 4-month follow-up. The third patient was a 42-yr-old woman with bleeding from a 6 x 4-cm aneurysm arising from the gastroduodenal artery. The injection of a chopped gelatin sponge failed to cause thrombosis of the aneurysm. The injection of cyanoacrylate in divided doses caused complete occlusion of the gastroduodenal and right hepatic arteries, with cessation of extravasation from the aneurysm. The patient remained well during a 3-month follow-up period, and repeat arteriography demonstrated proximal extension of the hepatic occlusion with no evidence of aneurysmal filling. The only complication encountered in any patient was transient epigastric pain. The results indicate that cyanoacrylate may be a valuable tool in intervention radiology.

7265 PRIMARY SMALL BOWEL PLASMACYTOMA WITH INTRACELLULAR FIBRILS. (Eng.) Harper, T. B., III.; Powers, J. M.; Russell, H. E.; Dunn, W. B., III, Gardner, W. A., Jr. (Charleston Veterans Admin. Hosp., 109 Bee St., Charleston, SC 29403). *Am. J. Gastroenterol.* 64(3):200-206; 1975.

The case of a 47-yr-old man with a rare plasma cell tumor, an extramedullary plasmacytoma arising in the small bowel, is presented. The patient presented with a 15-month history of nausea, postprandial vomiting, right upper quadrant pain, and weight loss. A tumor (located 20 cm distal to the ligament of Treitz), 20 cm of the surrounding bowel, and grossly enlarged mesenteric lymph nodes were removed at surggery. The patient remained asymptomatic until 1 yr later, when classical signs of multiple myeloma appeared. A subsequent laparotomy revealed tumor masses throughout the mesentery and omentum, producing fixation of the bowel to the anterior abdominal wall. The diagnosis of plasmacytoma was established by the microscopic finding of a neoplastic plasma cell infiltrate extending through the bowel wall from mucosa to serosa in the first surgical specimen. The tissue obtained at the second operation was similar to the initial tumor, although many of the plasma cells were more anaplastic with large nuclei, often binucleated, and had prominent nucleoli. Many of the cells contained paranuclear bundles of flexible and parallel fibrils that were 90 A in average diameter. Branches of the V or Y type were occasionally noted. This case is noteworthy because of the rarity and unusual course of the tumor and because of the presence of intracellular fibrils.

SMALL INTESTINE

Malabsorption

7293 THE VALUE OF TREHALASE ACTIVITY DETERMINATION RELATIVE TO PEDIATRIC INTESTINAL RESORPTION POTENTIAL. (Ger.) Fiehring, C.; Koslowski, H.; Jung, G.; Wedekind, U. (Kinderklinik, Medizinische Akademie, 50 Erfurt, Am Schwemmbach 32a, E. Germany). *Dtsch. Gesundheitsw.* 31(23):1091-1095; 1976.

Trehalase and other disaccharidase activity in normal and diseased intestinal mucosa was assayed. In 10 healthy children receiving 2 g/kg trehalose (TH) loading, the blood glucose increase was normal in 5 and negative in 5; 8 responded positively to lactose (LT) and 10 to maltose (MT) and saccharose (SH) loading, at 2 g/kg. In 17 children with malabsorption syndrome (MS), the result of MT, SH, and LT loading was normal, resp., in 10, 8, and 6 cases; TH was normal in only 7 of 17 patients. Jejunal samples (excised at the level of the ligament of Treitz) showed normal MT and SH, but no TH or LT activity in healthy children. No TH was found in the jejunal mucosa of 13 of 17 MS children; the remainder had high levels of 30-40 U/g wet weight. Comparison of TH loading and TH in jejunal biopsy was made in 16 children; there was no correlation in 8. In the other 8 children, a correlation between load and activity was positive in five, while a negative load result corresponded with deficient TH in three children. No significant difference in TH pattern of normal and MS bowel could be established. The independent determination of TH as an index of resorption in MS is meaningless.

7294 RADIOLOGICAL AND HISTOLOGICAL FINDINGS IN SIX PATIENTS WITH ALPHA-CHAIN DISEASE. (Eng.) Doe, W. F.; Henry, K.; Doyle, F. H. (Scripps Clinic and Res. Foundation, La Jolla, CA). *Br. J. Radiol.* 49(577):3-11; 1976.

The radiological and histological features of α-chain disease in six men (age, 18-36 yr) are described. The symptoms, present for 6 months to 6 year, included weight loss, diarrhea, abdominal pain (5 patients), wasting (4), gross finger clubbing (4), ankle edema (3), and elevated serum levels of alkaline phosphatase (5). On barium enema examination, all patients showed multiple fluid levels on erect films taken during the course of their follow-up examinations. In general, the abnormalities were more severe in the proximal and mid-small bowel than in the distal small bowel. Circular folds were thickened to a minor extent in five patients and grossly thickened in the duodenum and proximal jejunum in one. A nodular mucosal pattern was a striking feature in one, prominent in two, and present to a minor degree in two patients. Nodularity of the mucosal pattern was accompanied by a combination of scalloped and spiky contour in three patients. All patients showed some evidence of segmental dilatation that was not constant with time. Histological findings showed partial villous atrophy in one patient and subtotal villous atrophy in five, moderate numbers of crypts in one and sparse crypts in five, prominent diffuse plasma cell infiltration in one and massive diffuse infiltration in five, and low to normal luminal epithelium in all six patients. The histological and radiological assessment of the severity of the disease was similar in all but one case. α-Chain disease should be suspected in young men presenting with weight loss, diarrhea, abdominal pain, finger clubbing, and elevated serum alkaline phosphatase levels, especially in those geographical areas known to have a high incidence of intestinal infections.

7295 GASTROINTESTINAL BLEEDING AND IRON ABSORPTION IN THE EXPERIMENTAL BLIND LOOP SYNDROME. (Eng.) Giannella, R. A.; Toskes, P. P. (Veterans Admin. Hosp., Cooper Drive Div., Lexington, KY 40506). *Am. J. Clin. Nutr.* 29(7):754-757; 1976.

Gastrointestinal bleeding, vitamin B_{12} absorption, bacterial flora, and iron absorption were studied in the experimental blind loop syndrome. Ten-centimeter self-filling jejunal blind loops were constructed 10 cm distal to the ligament of Treitz in experimental male albino rats. Normal rats and rats in which self-emptying loops of the same size had been constructed at the same location served as controls. After a 5-ng orogastric dose of ^{57}CO-cyanocobalamin, normal rats absorbed a mean 64.2 ± 3.1%, rats with self-emptying loops, 62.8 ± 2.4%, and rats with self-filling loops only, 25.1 ± 4.2% of the dose. In rats with self-filling blind loops, the concentration of total aerobes and anaerobes was significantly increased in both the blind loop segment (BL; 8.3 ± 0.4 aerobes, 9.5 ± 0.2 anaerobes) and in the intestine distal to the blind loop (EJ; 8.1 ± 0.4 aerobes, 9.5 ± 0.3 anaerobes) compared to comparable intestinal segments from normal rats (BL, 7.2 ± 0.2 aerobes, 7.8 ± 0.2 anaerobes; EJ, 7.4 ± 0.3 aerobes, 7.0 ± 0.3 anaerobes) and from rats with self-emptying loops (BL, 6.9 ± 0.3 aerobes, 8.0 ± 0.2 anaerobes; EJ, 7.2 ± 0.3 aerobes, 7.7 ± 0.3 anaerobes. After an orogastric dose of 0.25 Ci ^{59}FeCl$_3$ and 0.25 mg of FeCl$_3$, rats with self-filling loops absorbed significantly more iron (15.2 ± 1.8%) than did normal rats (4.5 ± 0.69%). Only 1 of 20 normal rats and 0 of 6 rats with self-emptying loops had guaiac-positive stools, while 18 of 21 rats with self-filling loops had fecal blood loss. It is suggested that the documented gastrointestinal bleeding in rats with the experimental blind loop syndrome is another manifestation of damage to the intestinal epithelium in conditions of small intestinal bacterial overgrowth.

7296 THE ROLE OF SMALL BOWEL FOLLOW-THROUGH EXAMINATION IN THE DIAGNOSIS OF COELIAC DISEASE.

(Eng.) Masterson, J. B.; Sweeney, E. C. (Bristol Royal Infirmary, Bristol, England). *Br. J. Radiol.* 49(584):660-664; 1976.

The value of the barium follow-through examination in the diagnosis of celiac disease, jejunal biopsy histology, and clinical data were compared in 34 studies of 31 patients with proven celiac disease. Two of the patients had normal x-ray appearances, but jejunal histology showed partial villous atrophy. Two patients had abnormal x-ray appearances, but jejunal histology was normal. In 30 examinations, both x-ray and biopsy findings were abnormal. Seventeen of 25 patients (68%) showed steatorrhea, and 26 of 31 (83.7%) patients given d-xylose excretion tests showed decreased urinary excretion. The most common abnormal radiological signs were dilation of the bowel lumen (88%), thickened mucosal folds (88%), thickened duodenal folds (72%), segmentation/flocculation (65%), and sparse duodenal folds (50%). There were also assymmetrical duodenal folds in 45%, dilation of the duodenum in 36%, transient intussusception in 15%, prolonged transit time in 9%, and moulage in 3%. Abnormal small bowel follow-through examination due to diseases other than celiac disease was diagnosed in a group of 19 patients. The diagnoses were atrophic gastritis with small bowel bacterial contamination in five patients, diabetic enteropathy in five, gastric surgery with small bowel bacterial contamination in three, lymphoma of the small bowel in two, and Crohn's disease, tropical sprue, Whipple's disease, and chronic pancreatitis in one patient each. It is concluded that barium follow-through examination, despite its nonspecificity, is highly sensitive in detecting small bowel abnormalities in celiac disease, and has potential for revealing alternate causes of malabsorption. It may be performed on an out-patient basis, and is simple, inexpensive, and noninvasive.

7297 HL-A HISTOCOMPATIBILITY ANTIGENS IN PEDIATRIC CELIAC DISEASE.

(Ger.) Rotthauwe, H. W.; Rittner, Ch.; Waiyawuth, V.; Becker, M.; Tauberecht, I. (Universitats-Kinderklinik, 5300 Bonn, Adenauerallee 119, W. Germany). *Dtsch. Med. Wochenschr.* 101(22):849-854; 1976.

HL-A typing in celiac patients, their parents, and siblings is reported. The clinical sample consisted of 22 girls and 19 boys, 1-15 yr of age. Celiac disease (CD) was confirmed histologically by villous atrophy in the florid state or after gluten loading. There were 70 parents and 30 siblings from 40 families; 320 unaffected persons served as the control group. Five antigens in the CD group were significantly different from the control values. In locus SD-1, HL-A1 had a gene frequency (GF) of 0.3766 in 61% of CD compared to a GF of 0.1624 in 30% of the controls ($p<0.0005$); HL-A9 had a GF of 0.0362 in 7.3% of CD compared to 0.1148 in 23% of the controls ($p=0.02$). In locus SD-2, HL-A7 had a GF of 0.0362 in 7.3% of CD compared to 0.1428 in 27% of the controls ($p=0.02$), HL-A8 had a GF of 0.3558 in 59% of CD relative to 0.0874 in 17% of the control group ($p<0.0005$), and HL-A12 had a GF of 0.2190 in 39% of CD compared to 0.1402 in 26% of the controls ($0.025<p<0.05$). Both HL-A1 and HL-A8 were concomitant in 22 of the 41 cases; the common linkage of HL-A8 and HL-A12 was also significant. No elevated frequencies of HL-A12 were found in 14 cases of adult CD. No parent or sibling was clinically CD. One healthy child in each of six families was haplotypically identical with the relevant patient. A comparison of HL-A1,8 with a control subject revealed significant increases in the pediatric CD ($p<0.0001$) and in their parents ($p=0.025$), but not in their siblings. For haplotypes HL-A3,7 and HL-A2,12, there was no difference from the controls. Ethnic and genetic facts and factors from the literature are reviewed and discussed.

7298 CELLULAR INFILTRATE OF THE JEJUNUM AFTER RE-INTRODUCTION OF DIETARY GLUTEN IN CHILDREN WITH TREATED COELIAC DISEASE.

(Eng.) Lancaster-Smith, M.; Packer, S.; Kumar, P. J.; Harries, J. T. (Hosp. Sick Children, Great Ormond St., London WC1, England). *J. Clin. Pathol.* 29(7):587-591; 1976.

Lamina propria cells and intraepithelial lymphocytes of 22 children (aged 0.5-5 yr; mean, 2 yr) with celiac disease were studied to clarify the pathogenesis of the small bowel lesion of childhood celiac disease and to see if this differs from that found in adults. Six subjects were on a gluten-containing diet; two had villous atrophy of the jejunal mucosa and the other four were normal. Of 16 subjects who had been on an alleged gluten-free diet, 13 had a normal initial biopsy. After these 16 subjects had been placed on a gluten-containing diet for 3 months, 10 subjects had a significant mucosal lesion, while

3 remained normal. The mean numbers of plasma cells, lymphocytes, or eosinophils did not differ significantly from controls. The mean number of plasma cells was raised in celiac patients on gluten-containing diets (5,536 cells/mm^2) in comparison with that in 10 controls (2,531 cells/mm^2, $p<0.002$). In celiac patients studied serially, there was a significant increase in plasma cells after 3 months on a gluten-containing diet ($p<0.002$). The mean number of lymphocytes in the lamina propria of celiac patients on gluten-containing diets (947 cells/mm^2) was increased in comparison with controls (1,382 cells/mm^2, $p<0.01$). In the celiac patients studied serially, there was a significant fall in the number of lymphocytes after 3 months on a gluten-containing diet ($p<0.01$). The mean number of lamina propria eosinophils in the celiac patients on the gluten-containing diet (797 cells/mm^2) was significantly increased compared with controls (320 cells/mm^2, $p<0.01$). The mean number of intraepithelial lymphocytes in the celiac patients on both the gluten-free diet (39 lymphocytes/100 epithelial cells) and the gluten-containing diet (59 lymphocytes/100 epithelial cells) was increased compared with controls (30/100 epithelial cells, $p<0.002$ and 0.05, resp.). In patients studied serially, there was a significant increase after 3 months on the gluten-containing diet ($p<0.002$). A possible explanation for the reduction in lamina propria lymphocytes after the reintroduction of dietary gluten is that under the antigenic stimulus of gluten, sensitized lymphocytes transform into plasma cells, which is seen in adult patients. An alternative reason may be increased migration of the lymphocytes into the epithelial cell layer. The results are similar to those made in the adult form of the disease and suggest that more than one type of immunological reaction is involved in the pathogenesis of the jejunal lesion.

7299 MUCOSAL RECOVERY IN TREATED CHILDHOOD CELIAC DISEASE (GLUTEN-SENSITIVE ENTEROPATHY).

(Eng.) McNicholl, B.; Egan-Mitchell, B.; Stevens, F.; Keane, R.; Baker, S.; McCarthy, C. F.; Fottrell, P. F. (Regional Hosp., Newcastle, Galway, Ireland). *J. Pediatr.* 89(3):418-424; 1976.

Follow-up studies on 36 children, in whom celiac disease was established by gluten challenge, were carried out after management on gluten-free diets for a mean of 6 yr. Twenty-five normal siblings of children with celiac disease served as controls. The body weight was of almost normal distribution, with 17 of 36 children at or above the 50th percentile, whereas at initial diagnosis, only 3 of 32 whose weights were recorded were above the 25th percentile. Height was also of almost normal distribution. Mucosal morphology was regarded as normal (grade 0) in 16 and showed minimal or slight changes (grade 1) in 20. The epithelial cell height in 36 children in remission did not differ from controls; cell height was significantly higher in grade 0 than in grade 1 cases. Cell height at the time of initial diagnosis and following a gluten challenge (during active celiac disease) was significantly lower. Although the counts of interepithelial lymphocytes in 30 patients were within the normal range, the mean count for all 36 (827/1,000 epithelial cells) was significantly higher than that for controls (258/1,000). The mean count in grade 1 celiac disease was significantly higher than that in controls in grade 0. There was no significant difference between the counts of lamina propria lymphoid cells in 35 subjects and controls. The mucosal lactase level in the control subjects in both the duodenum (27.6 IU/g/protein) and jejunum (62.8 IU/g/protein) was significantly higher than in the patients in remission (19.2 and 22.7 IU/g/protein, resp.) and after the gluten trial (4.76 and 7.21 IU/g/protein, resp.). Mucosal sucrase was significantly lower in the jejunum of the patients in remission (57.6 IU/g/protein) and after gluten trial (9.0 IU/g/protein) than in the jejunum of the controls (86.9 IU/g/protein). A low content of mucosal lactase and increased numbers of interepithelial lymphocytes may be sensitive indicators of persisting ingestion of gluten in mucosa that is otherwise normal, or almost so, in appearance.

7300 L-ALANYL-L-PROLINE DIPEPTIDASE AND GLYCYL-L-VALINE DIPEPTIDASE IN MALABSORPTION SYNDROME.

(Ger.) Fernekorn, A.; Fiehring, C. (Kinderklinik, Medizinischen Akademie, Erfurt, E. Germany). *Z. Gesamte Inn. Med.* 31(9):266-269; 1976.

Dipeptidase and disaccharidase intestinal activity was assayed in the pediatric malabsorption syndrome. The clinical sample consisted of 45 children of both sexes with celiac disease, carbohydrate disturbances, and pathology of unclear origin. About half had been managed for a long period. Mucous membranes were excised from the proximal jejunum (ligament of Treitz). The enzymatic-mucosal correlations were as follows: for normal mucosa, subtotal villous atrophy, and total villous atrophy, the median enzyme levels in U/g wet weight were 41.2, 27.0, 18.5, resp., for L-ala-L-pro-dipeptidase; 500.3, 441.9, 266.0, resp., for gly-L-val-dipeptidase; 4.5, 3.9, 0.5, resp., for lactase; 54.6, 33.0, 18.6, resp., for maltase; 15.2, 11.9, 6.6, resp., for saccharase; and 8.4, 7.3, and 6.7, resp., for trehalase. Discrepancies between these patterns and the literature data are discussed.

7301 COWS' MILK PROTEIN INTOLERANCE: A POSSIBLE ASSOCIATION WITH GASTROENTERITIS, LACTOSE INTOLERANCE, AND IgA DEFICIENCY.

(Eng.) Harrison, M.; Kilby, A.; Walker-Smith, J. A.; France, N. E.; Wood, C. B. S. (Queen Elizabeth Hosp. Children, Hackney Rd., London, E2 8PS, England). *Br. Med. J.* 1(6024):1501-1504; 1976.

Twenty-five children with cows' milk protein intolerance were studied to determine the possible role of gastroenteritis in the etiology of cows' milk intolerance and the relation between cows' milk intolerance and lactose intolerance. Twenty children presented with an acute gastroenteritis characterized by profuse diarrhea and vomiting. An enteropathogenic *Escherichia coli* was isolated from the stool at the time of the acute episode in two children and 5 weeks later in another. There was circumstantial evidence of infective diarrhea in six children. Five children presented with chronic diarrhea or vomiting and failure to thrive. The serum immunoglobulin A (IgA) levels were below normal in 8 of 20 patients tested. After rehydration with i.v. fluids or a p.o. glucose and electrolyte mixture, all 20 children who presented with acute gastroenteritis failed to tolerate cows' milk. Sixteen of these children developed 0.5-2% reducing substances in the stools, and paper chromatography confirmed lactose malabsorption in the 13 tested. Disaccharidase activities were depressed in three of seven children. After 2-9 months on a lactose-free diet, none of the 20 children developed diarrhea when given 7% lactose feeds. Within hours of a milk challenge, diarrhea with abnormal amounts of reducing substances occurred in all 20 children and in an additional three of the total studied. Loss of disaccharidase activity was observed in five children who underwent biopsy after challenge. A pronounced increase in mucosal damage was seen, and this was accompanied by a rise in the number of Ig-containing cells in the lamina propria. Of the nine children who underwent biopsy before milk withdrawal, none had a normal small intestinal mucosa; two had subtotal villous atrophy, and one had a patchy lesion of moderate to subtotal villous atrophy. After the milk challenge, diarrhea occurred in all 25, occult blood in stools in 22 of 23, weight loss in 22 of 25, temperature rise in 19 of 24, and increased eosinophil count in 16 of 25. The evidence suggests that an acute attack of gastroenteritis may act as a triggering mechanism in the pathogenesis of cows' milk intolerance and that an IgA deficiency may be a predisposing factor, in that it allows the patient to become sensitized to a foreign protein.

7302 CONGENITAL SACCHARASE-ISOMALTASE DEFICIENCY. A SIX YEAR SURVEY. (Ger.)

Lucking, T.; Burdelski, M. (Kinderklinik Medizinischen Hochschule, 3000 Hannover 61, Karl-Wiechert-Allee 9, W. Germany). *Dtsch. Med. Wochenschr.* 101(23):897-900; 1976.

Five cases of pediatric saccharase-isomaltase deficit (SID) are reported. There were three girls, 4.75-5 yr of age, and two boys, 6 and 7.5 yr of age. All presented with diarrhea and three with developmental retardation at ages 1-6 weeks; diagnostic ages were 6-22 months. Saccharose doses (2 g/kg) elicited no rise in blood sugar in any patient. Glucose doses (2 g/kg) induced normal blood glucose elevation, as did maltose (2 g/kg) in four cases and lactose (2 g/kg) in three cases. The saccharose and lactose tests were pathological in only one child; lactose incompatibility was found also with milk products. Jejunal stereomicroscopy and histology were normal in all cases. All patients showed a marked reduction in saccharase (SH), isomaltase (IM), and maltase (MT) activity but lactase levels were normal. The range of SH levels was 0.8-3.1 U/g protein relative to 101.4 U/g for controls. IM levels were 2.2-3.8 U/g compared to 102.3 U/g for controls, while MT was 36.2-75.1 U/g relative to a control mean of 346.7 U/g. One child received saccharose-free nutrition for more than 1 yr, with improved fecal response and weight normalization. The lactose-intolerant child also received saccharase-free and milk-free diets; the intolerance eventually disappeared. Four patients were given Bi-myconase, containing acid-stable SH and γ-amylase, which hydrolyzes saccharose and isomaltose intraluminally. With this medication, restrictive diets could be interrupted. After 2 yr of age, all children showed increasing tolerance of saccharose and special management was not required beyond 2.5-3.25 yr of age. Two children presently experience occasional diarrhea after a high intake of sweets, but the other three cases are symptom-free.

7303 THE ENDOSCOPIC APPEARANCE OF THE DUODENUM IN WHIPPLE'S DISEASE. (Eng.)

Volpicelli, N. A.; Salyer, W. R.; Milligan, F. D.; Bayless, T. M.; Yardley, J. H. (Lovelace-Bataan Medical Center, 5200 Gibson Blvd., S.E. Albuquerque, NM 87108). *Johns Hopkins Med. J.* 138(1):19-23; 1976.

The case of a patient in whom fiberoptic duodenoscopy provided an early clue to the presence of Whipple's disease is presented. The patient, a 45-yr-old alcoholic man, presented with progressive weight loss, diarrhea, and intermittent abdominal pain. Sigmoidoscopy showed an edematous mucosa with small, shallow ulcers, and a rectal biopsy demonstrated numerous PAS-positive, Alcian blue-negative, granule-containing macrophages and scattered PAS-positive extracellular rods in the lamina propria, submucosa, and muscularis. The upper gastrointestinal series showed thickened mucosal folds, without thickening of the bowel wall, from the duodenum to the ileum. A jejunal biopsy showed PAS-positive macrophages by light microscopy and inclusions and rod-shaped bacteria typical of Whipple's disease by electron microscopy. Duodenoscopy showed that the mucosa in the second portion of the duodenum appeared to be partially covered with a yellow-white material; this was found to consist of enlarged villi interspersed with normal-looking mucosa. Histologically, these enlarged white villi were shown to contain a heavy accumulation of lipid and typical PAS-positive macrophages. After 1 yr of therapy with various combinations of tetracycline, streptomycin, and chloramphenicol, the patient was clinically improved; the duodenal mucosa was endoscopically normal and showed only a few PAS-positive macrophages.

LARGE INTESTINE

7319 ASCENDING RETROCECAL APPENDICITIS. (Eng.) Meyers, M. A.; Oliphant, M. (New York Hosp.-Cornell Univ. Medical Center, 525 E. 68th St., New York, NY 10021). *Radiology* 110(2):295-299; 1974.

The characteristic radiographic findings associated with ascending retrocecal appendicitis are described, and three illustrative cases are summarized. The distinctive x-ray signs are irregular nodularity (often restricted to a specific haustral row) and spastic inflammatory changes, which may involve the posterolateral wall of the ascending colon anywhere along its length from the cecum to the hepatic flexure. The position of the appendix may be inferred from the location of the ileocecal valve when the appendix itself cannot be visualized. Barium opacification of the appendix does not exclude the diagnosis of acute appendicitis. The appendix may demonstrate mass displacement, sinus tracts. or communication with the abscess cavity. A 50-yr-old man underwent a right hemicolectomy and ileotransverse colostomy for a presumed x-ray diagnosis of carcinoma of the colon. The pathological specimen revealed a perforated appendix with a periappendiceal abscess. Retrospective examination of the x-ray films revealed sinus tracts extending from the tip of the appendix. The preoperative roentgenographic diagnosis in a 64-yr-old woman with periumbilical and right lower quadrant pain was extraperitoneal lymphoma. Barium enema disclosed masslike infiltration of the lateral wall of the proximal ascendin colon associated with displacement of an opacified ascending retrocecal appendix. Appendicitis with periappendiceal abscess was diagnosed at surgery. A 52-yr-old man was evaluated for right-sided abdominal pain 3.5 months after an uneventful cholecystectomy. Barium enema revealed a long ascending retrocecal appendix with a localized gaseous collection distal to the opacified tip. The clinical impression was subphrenic abscess related to the previous surgery. Appendicitis with retrocecal abscess was demonstrated at surgery. The complex of roentgen findings, e.g., irregular nodularity and spastic inflammatory changes, distinguishes ascending retroceal appendicitis from such conditions as granulomatous or ischemic colitis, tuberculosis, amebiasis, and carcinoma.

7320 MASSIVE COLONIC BLEEDING AND ORAL CONTRACEPTIVE "PILLS." (Eng.) Prust, F. W.; Kumar, G. K. (William Beaumont Hosp., Royal Oak, MI 48072). *Am. J. Obstet. Gynecol.* 125(5):695-698; 1976.

The cases of two patients on oral contraceptives who developed massive colonic bleeding are presented. The first patient, a 48-yr-old woman who had been on oral contraceptives (Ortho-Novum 1/80) for 5 yr, had cramping lower abdominal pain and a 12-hr history of bloody diarrhea. The second patient, a 19-yr-old woman, had been taking ASA (8-10/week) for several weeks and had been on birth control pills (Orval) for approximately 3 months. In both patients, a barium enema examination revealed thumbprinting and spasm, primarily in the ascending colon and hepatic flexure. Both patients became asymptomatic after the withdrawal of oral contraceptives. The first patient also received prednisone (10 mg, 4 x daily) as therapy for vasculitis due to estrogen, and had further resolution of her symptoms. The onset, course, and follow-up of these patients suggest contraceptive-induced mesenteric mucosal injury resulting in massive bleeding.

7321 COLORECTAL CANCER--PROGNOSTIC SIGNS IN "LOCAL DISEASE." (Eng.) Lerner, H. J. (Dept. Surgery, Pennsylvania Hosp., Eighth and Spruce St., Philadelphia, PA 19107). *J. Surg. Oncol.* 7(5):395-402; 1975.

A brief review of the clinical and pathological signs that affect the prognosis of colorectal cancer patients is presented. A high degree of cellular aplasia is a bad prognostic sign, as is penetration of the bowel wall. Venous invasion and spread to lymph nodes are also associated with poorer survival. The extent of venous invasion appears to be related directly to the cellular anaplasia, and it may also be correlated with the depth of wall penetration and the extent of lymphatic spread. Tumors arising in the rectum may have a greater propensity to invade veins than tumors elsewhere in the colon. Colorectal cancer may also spread by perineural invasion. In 100 surgically resected rectal specimens, 47% had lymphatic spread, 30% had perineural invasion, and 20% had venous invasion. Local recurrence is twice as likely in cases with perineural spread. Pain is a late and bad prognostic sign. Cancers below the peritoneal reflection have a greater local recurrence rate than those of the intraperitoneal colon. Factors contributing to the increased rate of local recurrence are the rich plexuses of veins and nerves in the lower colon and rectum, the lack of a protective peritoneal wall below the reflection, and the presence of a large tumor in a rigid pelvis, which hinders exposure and limits a wide resection. Surgical manipulation may mobilize intravascular emboli. Acute obstruction and perforation significantly reduce the chances for cure.

7322 RADIOTHERAPY FOR CANCER OF THE COLON. (Eng.) Backhouse, B. M.; Howard, N. (Charing Cross Hosp., London W6, England). *Clin. Oncol.* 1(3):245-251; 1975.

The results of radiotherapy in 28 patients with carcinoma of the colon or cecum are reported in an attempt to assess the value of this type of therapy. All patients had undergone previous surgery, and were treated with radiotherapy because of incomplete resection of the tumor or because of recurrence. One group of 12 patients was considered to have a good response to radiotherapy (3,225-5,300 rads). In one patient, a poorly differentiated adenocarcinoma of the cecum showed complete regression, and the patient is alive after 10 yr. One tumor occurring in another patient also showed complete regression, and partial regression was seen in eight other cases. The treatment resulted in relief of pain and other symptoms in 7 of the 12 patients. In addition, healing of a fistula in one patient and of an ulcer in another were seen. The survival rate in these 12 patients was 6 months-10 yr. In a second group of three patients treated with 3,500-5,400 rads, the treatment resulted in only a 3-4 month survival rate, and produced relief of pain in only two patients. A third group consisted of two patients given radiotherapy immediately following hemicolectomy for carcinoma of the cecum, as a preventative measure. In neither case was there evidence of metastasis. The one patient followed up is free of recurrence 4 yr after radiotherapy. The fourth group of 11 patients consisted of patients who were too ill to benefit from radiotherapy or those with distant metastases. In the four treated patients (1,000-4,600 rads), the survival was 1-11 months. The treatment resulted in partial regression of a mass in one patient and in pain relief in two others. The results suggest that radiotherapy is useful in the treatment of recurrent or incompletely excised tumors, particularly for the relief of pain.

7323 A REAPPRAISAL OF STAGING AND THERAPY FOR PATIENTS WITH CANCER OF THE RECTUM. I. DEVELOPMENT OF TWO NEW SYSTEMS OF STAGING. (Eng.) Feinstein, A. R.; Schimpff, C. R.; Hull, E. W. (West Haven Veterans Admin. Hosp., West Haven, CT). *Arch. Intern. Med.* 135(11):1441-1453; 1975.

Two new systems of staging and therapy for patients with cancer of the rectum were developed and applied to a cohort of 318 patients. The first system, which is applied before treatment, is divided into four composite stages that contain elements of symptomatic, chronometric, comorbid, and paramorbid data, as well as information obtained from physical examination, sigmoidoscopy, and roentgenography. The second system, applicable to patients with resected tumors, is based on a combination of pretherapeutic clinical information and postsurgical anatomic evidence. The two systems produced prognostic gradients that were clinically distinctive and statistically effective in these patients: symptomatic stage, 43%; topographic extensiveness, 42%; location, 16%; prognostic comorbidity, 21%; anemia, 19%; gastrointestinal tract comorbidity, 16%; comorbid gastrointestinal tract symptoms, 11%; allied comorbidity, 12%; age, 16%; and sex, 15%. The data derived from symptoms and chronometry provide vital distinctions, undetectable from anatomic staging alone, about the rate of growth and functional effects of the cancer. The data derived from diverse aspects of comorbidity provide other vital distinctions about the underlying conditions of the patient. These new staging systems are concluded to achieve their increased effectiveness by incorporating the important prognostic information that has hitherto been omitted from existing classification systems for patients with rectal cancer.

7324 ANALYSIS OF PATIENT DISABILITY AFTER CURATIVE RESECTION FOR COLONIC AND RECTAL CANCER.

(Eng.) Orces, H.; Feldman, J.; Gardner, B.; Alfonso, A. (Dept. Surgery, Downstate Medical Center, State Univ. New York, Brooklyn, NY). *Am. J. Surg.* 131(1):98-102; 1976.

Ninety-seven patients undergoing curative resection for colonic or rectal cancer were investigated to determine the degree of early disability (disability 1-4 yr postoperatively). To provide descriptive data for another site in which disability is generally acknowledged to be more limited, a series of 209 patients undergoing curative radical mastectomy were similarly followed up. Follow-up data were maintained monthly for 3 months, every 3 months for the next 2 yr, and every 6 months thereafter. Despite the more advanced stage of disease in patients with breast cancer, the probability of death or disability during the 4-yr period was only 47%, compared to 73% in the patients with colonic or rectal cancer. However, 71% of the 58 patients who died of colonic cancer had no disability (they were ambulatory and required no more than minimal assistance) during the 3-month period prior to their death, compared with 53% of the 66 patients who died of breast cancer. During the 4 yr, only 19 patients with colorectal cancer had any disability, and 17 of these patients died within an average of 14 months after experiencing the disability. Eighty-six percent of patients undergoing curative resection for colonic or rectal cancer who survived 1 or 2 yr were not disabled. At the 3 yr interval, only 1 of 27 living patients was disabled, and at 4 yr, none of 14 living patients was disabled. Similar observations were noted among the breast cancer patients. These figures indicate that the probability of disability at a single point in time diminishes as the interval from curative surgery lengthens. The probability of disability among patients with colorectal cancer increased rapidly during the first 3 months after surgery to about 14% and then increased gradually to about 28% during the next 27-month period. In patients less than 65 yr old, the probability of death or disability at the end of the 4 yr was 55%; this was similar to that seen in the breast cancer patients (52%). For patients with colorectal cancer who were less than 65 yr old, the probability of disability (excluding death) increased to a peak of slightly less than 20% at 15 months after surgery and remained at that level throughout the study. These results suggest that the current policy of waiting 5 yr to determine cure in this disease wastes many years of active employment.

7325 DIVERTICULAR DISEASE: THREE STUDIES. PART I—RELATION TO OTHER DISORDERS AND FIBRE INTAKE. PART II—TREATMENT WITH BRAN. PART III—METABOLIC EFFECT OF BRAN IN PATIENTS WITH DIVERTICULAR DISEASE.

(Eng.) Brodribb, A. J. M.; Humphreys, D. M. (Radcliffe Infirmary, Oxford, OX2 6HE, England). *Br. Med. J.* 1(6007):424-430; 1976.

The actual fiber intake of patients with diverticular disease was compared with that of the general population, and the use of wheat bran in the treatment of diverticular disease was evaluated. Forty patients with diverticular disease comprised the study group, along with 80 age- and sex-matched controls. The crude-fiber intake for the patients was 2.6 g/day, for the control group, it was 5.2 g/day ($p<0.00003$). Crude fiber, a measure of the cellulose and lignin content, considerably underestimates the total dietary fiber, as hemicelluloses are not considered. A significantly increased incidence of hemorrhoids, varicose veins, abdominal hernias, hiatal hernia, and gallstones was noted in the patients. Treatment with wheat bran (24 g/day) for at least 6 months resulted in very satisfactory clinical responses in 33 cases. Sixty percent of all symptoms were abolished, and 28% of symptoms were exacerbated. Bran accelerated the transit time in 18 patients whose initial times were slower than 60 hr. It slowed the transit time in six patients whose initial times had been faster than 36 hr. In 15 patients with transit times of 36-60 hr, the time was unaffected by bran treatment ($p<0.006$). A significant increase was noted in stool weight ($p<0.0002$), and the number of intracolonic high-pressure waves decreased, especially those over 30 mm Hg during and after eating ($p<0.003$ and <0.0001, resp.). After 6 months of bran treatment, the oral glucose tolerance curve fell, fecal fat excretion increased, the serum lipoprotein pattern was altered, urinary calcium excretion was reduced, and the serum folate level fell. These changes do not contraindicate the use of bran in the treatment of diverticular disease. The findings support the concept that a fiber-depleted diet is a causative factor in diverticular disease. It is suggested that a high-fiber diet may not only relieve the symptoms of diverticular disease, but may also prevent the condition from developing.

7326 A CURRENT APPRAISAL OF PROBLEMS WITH GANGRENOUS BOWEL. (Eng.) Barnett, W. O.; Petro, A. B.; Williamson, J. W. (Dept. Surgery, Univ. Mississippi Medical Center, Jackson, MS). *Ann. Surg.* 183(6):653-659; 1976.

The hospital records of a group of 151 cases of bowel gangrene were analyzed. The overall mortality rate was 37%: 20% for 45 cases of hernia, 23% for 43 cases of adhesions, 74% for 42 cases of mesenteric insufficiency, and 28% for 21 cases of miscellaneous conditions resulting in gangrenous bowel. Among the cases of hernia, adhesions, and mesenteric insufficiency, mortality was higher in patients over 50. The mortality rate was 14% of 22 patients with inguinal hernia, 21% of 14 patients with umbilical or incisional hernias, and 2/3 patients with femoral hernia. Five of the hernia mortalities were deemed salvagable had better care or earlier treatment been available. Survival was related to prompt surgical intervention, as indicated by a 5% mortality rate for patients treated within 36 hr of the onset of symptoms and a 25% rate for those treated after 36 hr. Among 13 patients with adhesions who were treated within 36 hr, the mortality rate was 8%, compared to 25% for those treated later. The overall mortality of the 43 cases was 23%, 8 of which could have been prevented with better treatment and quicker surgical intervention. Among the 42 cases of mesenteric insufficiency, the diagnosis was made at autopsy in 8; 34 underwent surgical exploration. The mortality rate among eight who were treated within 36 hr was 37%, compared to 76% for those treated later. Among the 27 cases in which bowel resection was performed, the mortality rate was 40%. Of the total 42 cases, 3 could have been salvaged with more expeditious management. In all three groups, survival was better among patients who had more than 100 cm of bowel resected than among patients with less than 100 cm resected. This may be due to the more severe clinical symptoms in the former leading to a prompter intervention. The importance of early intervention is underscored, as is the liberal administration of antibiotics to delay intractable hypotension. Nasogastric tubes should not be used as definitive treatment for the patient with complete obstruction.

7327 A MAJOR ADVANCE IN THE MANAGEMENT OF PNEUMATOSIS COLI. (Eng.) Britten-Jones, R. (Lister House, 142 Ward St., North Adelaide, South Australia 5006). *Aust. N.Z. J. Surg.* 45(4):367-371; 1975.

The cases of two elderly patients with pneumatosis coli successfully treated by inhaling high concentrations of oxygen over a 5-day period are presented. The first patient, an 82-yr-old woman, had a 12-month history of diarrhea and a 6-month history of fecal incontinence. A mass was palpable in the region of the distal transverse and descending colon, and a polypoid cystic tumor was palpated through the rectum. Sigmoidoscopy revealed multiple submucosal cysts involving the upper half of the rectum and lower sigmoid colon, and histological examination and barium enema examination confirmed the presence of widespread pneumatosis coli. Treatment with codeine phosphate and Lomotil was unsuccessful. Within 24 hr of treatment with oxygen (administered continuously through an intranasal catheter at 12 l/min), the diarrhea had ceased. After 2 more days, the abdominal and rectal masses became impalpable, and a plain skiagram of the abdomen showed a marked reduction in the size of the cystic gas-filled spaces in the wall of the colon. After 5 days, sigmoidoscopy and barium enema examination revealed a normal rectum and sigmoid. The patient has been asymptomatic for 15 months. The second patient, an 82-yr-old man, had a 4-yr history of diarrhea and fecal incontinence. Cysts extended from the lower rectum to the mid-descending colon, and the bowel symptoms persisted despite treatment with Lomotil and codeine phosphate. After 4 days of treatment with oxygen (initial level 8 l/min, increased to 10 l/min), the diarrhea disappeared, and the next day, sigmoidoscopy and plain abdominal x-ray films were normal. If used with caution, oxygen treatment is a safe, simple, and effective method of treatment for pneumatosis coli.

7328 LESIONS ASSOCIATED WITH FAMILIAL POLYPOSIS COLI: STUDIES OF LESIONS OF THE STOMACH, DUODENUM, BONES, AND TEETH. (Eng.) Ushio, K.; Sasagawa, M.; Doi, H.; Yamada, T.; Ichikawa, H.; Hojo, K.; Koyama, Y.; Sano, R. (Dept. Diagnostic Radiology, National Cancer Center Hosp., Tsukiji 5-1-1, Chuoku, Tokyo, Japan). *Gastrointest. Radiol.* 1(1):67-80; 1976.

The entire gastrointestinal tract and bones of 24 patients with familial polyposis coli were examined after a routine medical examination. Polypoid lesions of the stomach were observed in 15 of 22 cases. The lesions were always multiple, and were scattered all over the stomach, with the highest incidence in the gastric body and fornix. In one case, multiple adenomas with atypical epithelium and microscopic intramucosal adenocarcinoma were detected in the lower part of the stomach, while atypical epithelium was detected in the pyloric gland areas in another patient. No correlations were observed between the number of polyps in the stomach and polypoid lesions in the large intestine. Of 10 cases in which duodenal examinations were performed, polypoid lesions were found in 9, and adenomas were found in 5. Exostosis, osteomatosis, and cortical thickening were observed in 9 of 18 patients undergoing bone survey. Panoramic radiography of the maxilla and mandible was carried out in 16 cases, and multiple osteosclerotic areas of the mandible were observed in 13. Soft tissue tumors were observed in three cases, and ileus attributable to mesenteric desmoid tumor was observed in one case. Familial polyposis coli is a disease that produces polypoid lesions not only in the large intestine, but in the stomach and duodenum as well. The authors also conclude that familial polyposis coli and Gardner's Syndrome are similar, and that both should be regarded as a systemic disease with a predisposition to multiple tumor formation.

7329 THE RADIOLOGICAL DEMONSTRATION OF COLORECTAL POLYPS UNDETECTED BY ENDOSCOPY. (Eng.)

Laufer, I.; Smith, N. C. W.; Mullens, J. E. (McMaster Univ. Medical Centre, Hamilton, Ontario, Canada L8S 4J9). *Gastroenterology* 70(2):167-170; 1976.

The value of double contrast radiology in the detection of colorectal polyps occurring in potential endoscopic blind spots was illustrated in a survey of 800 routine double contrast studies of the colon. In this series, 119 polyps were diagnosed radiologically in 78 patients. Follow-up studies were available in 46 patients with 72 polyps; only 56 of these polyps were found on the initial endoscopic examination. Of the remaining 16 polyps, repeat endoscopy revealed 5 polyps, and repeat radiology revealed 1 polyp. Repeat radiology revealed that there was no polyp in six cases, and there was no further investigation in the four remaining cases. The polyps that were missed by the initial endoscopic examination were usually located in the rectum behind the valve of Houston or in any area of the colon where there was sharp angulation. Three cases illustrating these blind spots are presented. In the first patient, the initial double contrast study demonstrated a 1-cm polyp in the distal transverse colon just proximal to the splenic flexure; repeated colonoscopic examinations failed to demonstrate this lesion. The double contrast study was repeated, and the polyp was finally found and removed at a subsequent colonoscopic procedure. In the second patient, a 1-cm polyp in the descending colon where the junction of the sigmoid and descending colon resulted in sharp angulation was overlooked at the initial colonoscopic examination. In the third patient, the hidden lesion occurred in the rectum just behind the valve of Houston. These cases illustrate the importance of high quality radiological study of the colon and the complementary nature of radiology and endoscopy in the detection of colorectal polyps.

7330 VOLVULUS OF THE COLON--A CONTINUING SURGICAL PROBLEM. (Eng.)

Nemer, F. D.; Hagihara, P. F.; Mays, E. T.; Griffen, W. O., Jr. (Dept. Surgery, Univ. Kentucky Coll. Medicine, Lexington, KY 40506). *Dis. Colon Rectum* 19(4):321-329; 1976.

A retrospective analysis of 26 cases of volvulus of the colon is presented. All but three had significant associated diseases. The duration of obstructive symptoms varied from 8 hr to 5-6 days. Abdominal distention was universally present, and nausea and vomiting were common. A plain film of the abdomen suggested the diagnosis in 25/26, and only eight cases required confirmation by barium enema. The sigmoid was the involved site in 15, the cecum in 10, and the transverse colon in 10. Barium studies were diagnostic in five cases of sigmoidal volvulus and therapeutic in two. They were diagnostic in three cases of cecal vovulus, but therapeutic in none. Three patients were not subjected to operation. One moribund patient died within 30 min of admission, and two patients with sigmoidal volvulus were decompressed by proctoscopy or colonoscopy. Of the remaining 23, 16 underwent emergency surgical procedures, 5 of which died postoperatively. Seven patients underwent elective surgery, and there was no associated mortality. The overall mortality in the series was 5/26 (3/10 cecal, 1/15 sigmoidal, and 1/1 transverse colon). Necrotic bowel was found in only one of the postoperative deaths, indicating that the need for emergency surgery, not necrotic bowel per se, was the principal cause of death in these generally debilitated patients. Six of the seven patients who underwent elective procedures had been converted from emergency to elective surgical status by nonoperative decompression, and the seventh underwent an elective procedure after a sixth recurrence. It is suggested that conversion to elective operative status by nonsurgical means will improve the mortality rate, and such a plan of treatment is outlined.

7331 VOLVULUS OF THE SIGMOID COLON IN BRAZIL: A REPORT OF 230 CASES. (Eng.)

Gama, A. H.; Haddad, J.; Simonsen, O.; Warde, P.; Manzione, A.; Da Silva, J. H.; Ioshimoto, M.; Cutait, D.; Raia, A. (Faculdade de Medicina, Universidade de Sao Paulo, Rua Padre Joao Manoel, 800 apto. 11, 01411 Sao Paulo, Brazil). *Dis. Colon Rectum* 19(4):314-320; 1976.

The etiology, pathophysiology, diagnosis, and treatment of sigmoidal volvulus are reviewed and a series of 230 cases (average age, 40 yr) treated since 1938 is presented. Both congenital and acquired factors have been implicated in the etiology, and in Brazil, sigmoidal volvulus is thought to be a frequent complication of megacolon resulting from Chagas' disease. Among 35 patients treated by 60 surgical procedures in the period 1938-1952, there were 9 deaths, compared to 7/86 in 1953-1964 and 4/109 in 1965-1974. In the entire series, there were 54 recurrences: 35 following simple surgical detorsion and 9 following endoscopic emptying of the volvulus. Of the total of 20 deaths, 15 were due to peritonitis and 5 to miscellaneous causes. Recommended treatment consists of endoscopic emptying in cases without clinical, x-ray, or endoscopic signs of intestinal ischemia. In cases of complicated volvulus or when a loop cannot be emptied, laparotomy is indicated. When a simple volvulus is found at surgery, the loop should be untwisted and the gaseous contents siphoned off via a rectal catheter. The Hartmann operation is recommended in cases of necrotic bowel. Because of the frequency of recurrence following endoscopic emptying or surgical detorsion, definitive treatment of the megacolon should be carried out as soon as possible after initial treatment of the volvulus.

LARGE INTESTINE

Ulcerative Colitis

7381 STUDY OF THE ULTRASTRUCTURAL PATHOLOGY OF ULCERATIVE COLITIS. (Ger.) Otto, H. F.; Gebbers, J. O.; Muller-Wieland, K. (Pathologisches Institut der Universitat, D-2000 Hamburg 20, Martinstr. 52, W. Germany). *Virchows Arch.* [*Pathol. Anat.*] 367(2):113-130; 1975.

An electron microscope study of membrane modification and cell interaction in ulcerative colitis (UC) is reported. Biopsies were taken from 37 UC patients, all less than 50 yr of age, either at the time of onset or during a crisis. Epithelial hyperplasia was marked, especially superficially and deep in the mucosal crypts. Columnar cell microvilli were rarefied. There was a plethora of small round bodies both in normal and UC colonic mucosa. The glycocalices showed acute changes. In the basal region of the lamina, epithelialis mucosae membrane folds were linked to lymphocyte clusters. The interepithelial spaces appeared narrow and the epithelial cells contained intranuclear areas of round granular or long, membrane-bound structures. Interepithelial lymphocyte numbers were abnormally high; eosinophils were confined to the crypt abscesses. In the stratum proprium mucosae, the inflammatory infiltrate consisted mainly of small lymphocytes and plasma cells. The lymphocyte cytoplasm was organelle-rich, with extensive processes and micropinocytotic vesicles; the nuclei were deeply invaginated. The full spectrum of plasma cells was present, unlike normal colon, especially Turk cell types containing Russel bodies. The number of macrophages was abnormally high, even more than that in colon carcinoma. Their cytoplasm was filled with phagolysosomes and ingesting vesicles; the processes were typically fingered. The phagocytic cells with dense bodies, well-developed Golgi apparatus, and light cytoplasm were clearly differentiated from macrophages. Abnormally high numbers of mast cells were found in mucosal stroma and were directly related to enterochromaffin cells; some contained dense homogeneous inclusions. The various cell assemblies are seen as expressions of functional interaction and integration and the cell modifications as expressions of an incomplete mucosa-block, associated with immunoglobulin A and secretory-piece deficit.

7382 RESPONSES TO DRUG THERAPY IN ULCERATIVE COLITIS. EVALUATION BY RECTAL BIOPSY AND MUCOSAL CELL COUNTS. (Eng.) Korelitz, B. I.; Sommers, S. C. (Lenox Hill Hosp., 100 East 77th St., New York, NY 10021). *Am. J. Dig. Dis.* 21(6):441-447; 1976.

Using the technique of cell counting, rectal biopsies of active untreated ulcerative colitis and of treated cases with positive or negative sigmoidoscopic findings were analyzed to evaluate response to medical therapy. The effects of the administration of salicylazosulfapyridine (SAS), prednisone, and 6-mercaptopurine, singly and in combinations, were analyzed and compared statistically with the results of the ulcerative colitis and noncolitis control groups. Active disease was associated with decreased epithelial goblet cells and increased fragmented nuclei. Lamina propria eosinophils decreased with successful responses to therapy. SAS was correlated with reduced chronic inflammation, as indicated by fewer plasma cells. Prednisone was associated with significantly diminished acute inflammation, as reflected by decreased neutrophils. Treatment with 6-mercaptopurine was followed by a reduction in both acute and chronic inflammation and an increase in mast cells. Macrophages, indicators of resolving inflammation, were significantly increased after drug combinations that included 6-mercaptopurine. It is concluded that a new and potentially successful method for evaluating the effects of medical treatment and individual drug therapy in the management of ulcerative colitis has been demonstrated.

LARGE INTESTINE

PANCREAS

7388 ANGIOGRAPHY IN DISEASE OF THE PERIPANCREATIC LYMPH NODES. (Eng.) Tylen, U. (Dept. Diagnostic Radiology, Univ. Hosp., S-221 85 Lund, Sweden). *Acta Radiol.* [*Diagn.*] *(Stockh.)* 16(6):625-632; 1975.

Angiography was performed in six patients with malignant lymphoma, three of whom had reticulum cell sarcoma, and in two patients with metastatic involvement of the peripancreatic lymph nodes. Angiography of the celiac and superior mesenteric arteries was done in all the cases in antero-posterior and right posterior oblique projections; in three patients lateral views were also done. The three patients with reticulum cell sarcoma showed stenosis of the splenic artery; the stenosis had an irregular outline in two. In all three, the tail of the pancreas was richly vascular, and the small arteries were tortuous and irregular. The splenic vein was occluded in one case and severely stenosed in two. The lateral views showed the main stem of the superior mesenteric artery to be displaced ventrally. Of the three patients with other malignant lymphomas, two had slight smooth long tapering stenosis in the splenic and hepatic arteries. The gastroduodenal artery and the pancreatic arcades were displaced and stretched in two patients, due to an avascular expansive lesion. The superior mesenteric artery was displaced ventrally in one patient, and the portal and splenic veins were stenosed in one patient each. Metastasis of a seminoma to the lymph nodes around the pancreas in one patient caused displacement of the gastroduodenal and the pancreatic arcades. The patients with metastases to the peripancreatic lymph nodes from a prostatic carcinoma had complete stenosis of the celiac artery and a long smooth stenosis of the common hepatic artery. The pancreatic arcades were dilated and tortuous, presumably due to collateral circulation from the superior mesenteric artery. In the entire series of eight patients, four showed displacement of the kidney pelvis or ureter by enlarged lymph glands. The findings were similar, in general, to those of pancreatitis and pancreatic carcinoma. The results demonstrate that vascular abnormalities demonstrated by angiography are often unspecific.

7389 SMALL BOWEL STRUCTURE AND FUNCTION IN PANCREATIC STEATORRHEA. (Eng.) Bank, S.; Marks, I. N.; Novis, B. H. (J. 1 Observatory, Groote Schuur Hosp., Cape Town, 7925 South Africa). *Mt. Sinai J. Med. N.Y.* 42(6):552-564; 1975.

The applicability of direct and indirect tests of small bowel function and structure to patients with pancreatic steatorrhea was evaluated. The most common abnormality was a diminished absorption of a 25-g load of D-xylose (<4.3 g in 5 hr) found in 6/60 patients. Grossly impaired vitamin B_{12} absorption occurred in 4 (<3% of administered dose in 24 hr), and 30% had urinary excretion levels (3%-8%) compatible with small bowel malabsorption. Very high chemical fecal fat levels, >25 g/day, appeared in three patients who handled fatty foods poorly. Partial villous atrophy of the jejunal mucosa was noted in only four patients. One patient had an increased urinary indican excretion. No patient demonstrated protein-losing enteropathy, and the disaccharidase activity of the small bowel mucosa was not impaired quantitatively and qualitatively. An abnormal or frankly diabetic glucose tolerance test was noted in 93% of the patients. Pancreatic replacement therapy and total dietary fat restriction improved B_{12}, xylose, and free fatty acid abnormalities, but not to normal levels. Although reproducible results were not always achieved, normal and abnormal values could be separated on successive testing. The abnormal tests did not constitute associated small bowel malabsorption, but they may present a physical defect of absorption due to intraluminal factors associated with the steatorrhea. The finding of two or more abnormalities in the same patient suggests the presence of associated small bowel disease.

7400 THE BEHAVIOR OF MUCOPOLYSACCHARIDE IN THE PANCREATIC JUICE IN CHRONIC PANCREATITIS. (Eng.) Wakabayashi, A.; Takeda, Y. (Second Dept. Medicine, Osaka Medical College, 2-7, Daigaku-cho, Takatsuki, 569, Japan). *Am. J. Dig. Dis.* 21(8):607-612; 1976.

The behavior of hexosamine in the pancreatic juice was studied in 37 patients with chronic pancreatitis, 6 with alcoholism, 13 with gallstones, and 11 with peptic ulcers. After a 10-min basal sample of the duodenal contents (during a fast) was taken, pancreozymin (1 U/kg, i.v.) was injected, and the duodenal contents were collected for an additional 40 min. Then secretin (1 U/kg) was injected, and the duodenal contents were collected for 60 min. The hexosamine concentration in the fraction taken 20-40 min following secretin injection was taken as the measure of pancreatic hexosamine in the duodenal aspirate. There was a negative correlation between hexosamine concentration and either the volume output or the bicarbonate output in this fraction. The hexosamine concentration was 0.034 ± 0.005 mg/ml in the controls and 0.163 ± 0.028 mg/ml in suspected chronic pancreatitis, 0.198 ± 0.043 mg/ml in established chronic pancreatitis, 0.108 ± 0.029 mg/ml in alcoholism, 0.051 ± 0.010 mg/ml in gallstone, and 0.055 ± 0.010 mg/ml in peptic ulcer patients. The values in alcoholism and chronic pancreatitis were significantly higher than those in controls ($p<0.05$). Hexosamine levels were 0.261 ± 0.072 mg/ml, in alcoholic pancreatitis, followed by 0.197 ± 0.102 mg/ml in idiopathic pancreatitis, 0.112 ± 0.038 mg/ml in pancreatitis caused by gallstones, 0.379 ± 0.085 mg/ml in chronic relapsing pancreatitis, and 0.113 ± 0.027 mg/ml in chronic nonrelapsing pancreatitis. Among the 22 established cases of pancreatitis, the value was 0.230 ± 0.226 mg/ml in 11 cases of chronic noncalcifying pancreatitis, as opposed to only 0.116 ± 0.089 mg/ml in 11 cases of chronic calcifying pancreatitis. The results suggest that rises in hexosamine concentration can be caused by alcohol ingestion and that the high values in relapsing alcoholic pancreatitis may be due to mucosubstance increases related to acute attacks accompanying ductal obstruction.

7401 PANCREATITIS AND THE BATTERED CHILD SYNDROME: REPORT OF 2 CASES WITH SKELETAL INVOLVEMENT. (Eng.) Slovis, T. L.; Berdon, W. E.; Haller, J. O.; Baker, D. H.; Rosen, L. (The Children's Medical and Surgical Center, 622 W. 168 St., New York, NY 10032). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 125(2):456-461; 1975.

Two cases illustrating the clinical and roentgenographic spectrum of traumatic pancreatitis in children are presented. The first patient, a 2-yr-old boy, presented with vomiting, a bruised, tender abdomen, and lethargy following a beating. He became oliguric, the blood urea nitrogen level rose to 80 mg%, and he developed hematuria. The initial skeletal survey was normal. Three days after admission, an i.v. pyelogram showed normal kidneys, and an upper gastrointestinal series showed a widened duodenal sweep with edematous changes. The patient slowly recovered with supportive therapy and antibiotics. He developed widespread painful skeletal lesions on the 17th hospital day. Roentgenograms of the feet showed widespread intramedullary necrosis of the metatarsals and phalanges and considerable periosteal new bone reaction. Larger destructive lesions in the tibial metaphysis were also noted. The upper extremities, which were clinically normal, showed medullary destruction and periosteal new bone reaction. Diffuse bone lesions accompanying pancreatitis were diagnosed. The patient recovered without treatment. The second patient, a 19-month-old girl, presented with hematemesis, hypoactive bowel sounds, a nontender abdomen, lethargy, and oliguria. A plain film of the abdomen revealed no evidence of free air and only a dilated loop of jejunum. An upper gastrointestinal series showed a widened duodenal sweep and thick small bowel folds. An i.v. pyelogram showed the liver displaced medially by ascites and normal kidneys. A bone survey showed long bone fractures, but was otherwise normal. A repeat upper gastrointestinal series showed duodenal obstruction, with a mass impinging on the medial aspect of the descending duodenum. Laparotomy revealed peritonitis secondary to acute hemorrhagic pancreatitis. There was extensive necrosis of the omentum and transverse mesocolon reflecting leakage of pancreatic enzymes. The entire pancreas was indurated and hemorrhagic, as were the structures of the lesser sac. The mass obstructing the duodenum was an abscess, and drainage was mandatory. The patient slowly recovered on hyperalimentation, and she was discharged 3 months after admission. Repeat skeletal survey failed to show evidence of medullary necrosis with periosteal new bone reaction. These cases indicate that diffuse periosteal reaction, lytic lesions, ascites, duodenal obstruction, and the roentgenographic signs of pancreatitis should now be included among the findings in the battered child syndrome.

LIVER AND BILIARY TRACT

7427 THE ENTEROHEPATIC CIRCULATION OF BILE ACIDS IN MAN. (Eng.) Hofmann, A. F. (Mayo Clinic, Rochester, MN 55901). *Wis. Med. J.* 75(5):J35-40; 1976.

The enterohepatic circulation of bile acids in man is reviewed. General topics covered include the chemistry and physiology of bile acids, methods for characterizing the enterohepatic circulation in man, chenic acid therapy in patients with gallstones, and the diagnostic use of bile acids. The observation that chenic acid administration to patients with gallstones decreases the cholesterol saturation level of their bile by transforming it from saturated or supersaturated to unsaturated has given rise to extensive clinical trials aimed at determining the efficacy and safety of chenic acid. Multiple small stones are much more responsive than large single stones to chenotherapy, not only because the latter have a lower surface to volume ratio, but also because the latter are older and often coated by calcium. Chenic acid appears capable of decreasing the cholesterol saturation level of the bile in most patients (perhaps more than 90%) when administered in sufficient amounts, and failure of gallstones to dissolve most often indicates that the stone is not a cholesterol stone or is coated with calcium. The only common side effects resulting from chenic acid therapy in about 5,000 patients have been transient, slight elevations in SGOT and SGPT, which frequently are self-limited, despite continuous treatment. Although the long-term future of chenotherapy is uncertain, it does appear to be the treatment of choice for patients with increased risk for cholecystectomy.

7428 DESFERRIOXAMINE B: REVERSIBLE SIDE EFFECTS OF HIGH DAILY DOSES. (Eng.) Cartei, G.; Barbui, T.; Cazzavillan, M.; Chisesi, T.; Dini, E. (Reparto di Ematologia, Ospedale Civile Regionale, 36100 Vicenza, Italy). *Blut* 31(1):11-16; 1975.

Possible side effects of large daily doses of deferoxamine (Desferrioxamine B; DF) in 16 patients with iron overload due to chronic liver and hematologic diseases were investigated. The daily doses that were given for 5 consecutive days ranged from 1 to 4 g. The first gram was given i.m., while supplementary amounts were administered by two i.v. slow infusions in saline. Doses of 1 and 2 g/day had no side effects, with the exception of a drop in the WBC count from 4,600-5,200 to 2,800 cells/mm^3 after 5 days of therapy in a 72-yr-old man with sideroblastic anemia. A dose of 3 g/day was given to 15 patients, and this was followed in four cases by some elevations in liver or kidney function tests. Urea was raised from 15-17 to 30 mg/100 ml in a 62-yr-old female, and creatinine was raised from 1.0-1.3 to 2.0 mg/100 ml in a 59-yr-old male. Serum alkaline phosphatase was raised from 35-43 to 60 mU/ml in a 67-yr-old female, and serum glutamyl-transpeptidase was increased from 90-120 to 218 mU/ml in a 37-yr-old male. Following the administration of 4 g/day of DF to a 76-yr-old male, creatinine, SGOT, and SGPT values were raised from 1.4-1.9 to 3.6 mg/100 ml, 12-20 to 96 mU/ml, and 9-20 to 96 mU/ml, resp. The same dose caused elevation in creatinine (0.4-0.8 to 1.5 mg/100 ml) and in serum alkaline phosphatase (50-60 to 87 mU/ml) in a 67-yr-old female. The same 4-g daily dose also caused an elevation in LDH (50-68 to 115 mU/ml) in a 38-yr-old male. WBC counts fell below the pretreatment range in three patients receiving daily doses of 3-g and in four patients receiving daily doses of 4-g. All of the above variations disappeared within 1 week following the reduction in the daily dosage to 1-g. It is suggested that the administration of doses of DF greater than 2-g/day should be avoided, at least in older patients. When large doses of DF are needed, as in acute iron poisoning, liver and kidney function, as well as the hematologic picture, should be carefully surveyed.

7429 A STUDY OF FACTORS INFLUENCING DRUG DISPOSITION IN CHRONIC LIVER DISEASE, USING THE MODEL DRUG (+)-PROPRANOLOL. (Eng.) Branch, R. A.; James, J.; Read, A. E. (Dept. Medicine, Univ. Bristol, Bristol BS8 1TD, England). *Br. J. Clin. Pharmacol.* 3(2):243-249; 1976.

Factors influencing drug disposition in chronic liver disease were studied in 6 normal controls and in 20 patients with stable chronic liver disease, following the i.v. administration of 40 mg of (+)-propranolol. There was a progressive increase in the half-life (T½) of (+)-propranolol from a mean of 2.9 hr in controls to 9.8 hr in patients with mild chronic liver disease and 22.7 hr in patients with severe chronic liver disease. This prolongation was associated with a twofold increase in the volume of distribution, a fourfold decrease in the clearance of (+)-propranolol, a decrease in serum albumin, an increase in serum bilirubin, and a prolongation in the prothrombin index (all of which were significantly correlated). In both the patients with liver disease and normal subjects, the clearance of (+)-propranolol correlated with the clearance of indocyanine green ($p<0.05$). Protein was reduced from 87.8% (mean value) in normal subjects to 82.3% ($p<0.05$) in patients with chronic liver disease, but this change was not related to changes in plasma proteins. In normal subjects and patients without ascites, the volume of distribution increased with decreases in protein binding. The five patients with ascites had a similar correlation, except that the volume of distribution was increased twofold for any degree of protein binding. The results indicate that chronic liver disease tends to influence the three major independent variables that determine the T½ of (+)-propranolol in such a way that increases in plasma protein pool size, decreases in protein binding, and decreases in clearance with all tend to prolong the T½.

7430 HEPATORENAL SYNDROME FOLLOWING HEMIHEPATECTOMY. (Eng.) Epstein, M.; Oster, J. R.; De Velasco, R. E. (Veterans Admin. Hosp., 1201 N.W. 16th Street, Miami, FL 33125). *Clin. Nephrol.* 5(3):128-133; 1976.

A case of hepatorenal syndrome (HRS) following right hemihepatectomy in a previously healthy 21-yr-old male patient who sustained a shotgun wound in the abdomen is reported. In spite of the development of severe oliguric renal insufficiency and the administration of 7 l of saline, albumin, and blood/day in excess of losses, along with the administration of furosemide, the urine sodium concentration (about 10 mEq/l) from the 4th postoperative day remained very low, thereby excluding the diagnosis of acute tubular necrosis. Although severe hyperbilirubinemia developed, the prothrombin time was only slightly abnormal, and the liver doubled in size within 2 weeks of surgery. The patient expired from a cardiac arrest during an emergency laparotomy on the 14th day after initial surgery. At autopsy, the kidneys were found to be enlarged, but without evidence of pre-existing chronic renal disease. Although the precise pathophysiological mechanism operating in this patient is not clear, an absence of severe hepatic failure militates against the concept of a circulating substance toxic to the kidney being the sole etiologic factor. Rather, the present case raises the possibility that an alteration of hemodynamics may participate in mediating the HRS.

7431 EFFECT OF BILE DUCT LIGATION ON THE ULTRASTRUCTURAL MORPHOLOGY OF HEPATOCYTES. (Eng.) Vial, J. D.; Simon, F. R.; Mackinnon, A. M. (Dept. Molecular, Cellular, and Developmental Biology, Univ. Colorado, Boulder, CO 80220). *Gastroenterology* 70(1):85-92; 1976.

The effect of severe cholestasis produced in male Sprague-Dawley rats by bile duct ligation of surface membrane ultrastructure was examined. In the hepatocytes of the rats with cholestasis, the intratrabecular surfaces were folded, and numerous structures, such as spherules and scattered finger-like processes, were present. The number and prominence of the laminar plicae expansions were increased, and they were generally flattened against the cell body. The lumina of the bile canaliculi were widened, and their course appeared more tortuous than that in controls. In the normal livers, the canaliculus was bounded on either margin by a marginal ridge along which a row of microvilli overhanging the lumen rose. A comparison of scanning electron microscopic and transmission electron microscopic images of normal livers with the livers of animals that underwent biliary duct ligation showed that among the villous population of one canaliculus, there appeared to be a special class formed by the villi implanted on the marginal ridge. The villi derived from the marginal ridge were unaltered after bile duct obstruction. In contrast to the hepatocytes of normal rats, the remainder of the canalicular surface in the hepatocytes of rats with bile duct ligation was devoid of microvilli. Newer techniques in tissue preparation and scanning electron microscopy demonstrate that bile canalicular microvilli are derived from two anatomical sites and respond differently to bile duct ligation.

7432 BILIARY LIPID EXCRETION AFTER HEPATIC PORTOENTEROSTOMY. (Eng.) Lilly, J. R.; Javitt, N. B. (Univ. Colorado Sch. Medicine, 4200 E. Ninth Ave., Denver, CO 80220). *Ann. Surg.* 184 (3):369-375; 1976.

Experience with 16 infants treated for biliary atresia by hepatic portoenterostomy employing an exteriorized Roux-en-Y intestinal segment is presented. The sequential biliary lipid content in the bile and serum after the operation was determined, and the biochemical studies were correlated with the clinical course of the infants following the operation. Eleven infants had sustained postoperative bile drainage, but four of these had progressive liver cirrhosis. In the seven patients with bile drainage and stable or improved hepatic function, the total serum bilirubin increased several mg/100 ml early in the postoperative period. Several weeks later, there was a gradual decline in serum values coincident with increased bile output, and the bilirubin levels reached normal 6-24 weeks after portoenterostomy. In these patients, the total serum bile acid dropped by over two-thirds in the first two postoperative months, and thereafter the decline was more gradual. The highest single preoperative level in these patients was 155 µg/ml, and the lowest postoperative value was 9 µg/ml. Preoperatively, the serum bile acid components were almost equally divided between cholate and chenodeoxycholate. The initial fall in total bile acid was largely due to the decrease in the cholate fraction; subsequently, the decline in the cholate and chenodeoxycholate fractions was about equal. In the bile, the total bile salt concentration was highest during the first months after operation, and the cholate fraction contributed most to bile salt excretion throughout the first postoperative year. A sharp decrease in the elevated serum cholesterol and phospholipid values was seen during the first months after operation, after which they fell gradually to normal or near normal levels by the ninth postoperative month. Bile cholesterol and phospholipids increased progressively during the first five postoperative months, correlating better with bilirubin excretion than with biliary bile salt concentrations. In the patients with bile drainage and cirrhosis, the preoperative and early postoperative values of serum and biliary bilirubin and bile lipids were not significantly different from those of the patients with improved liver function; preoperative serum bilirubin, cholesterol, phospholipid, and total bile acid levels declined during the first 1-2 months, but this trend was reversed between 2 and 3 months, and the serum bilirubin and lipid values subsequently increased beyond those recorded preoperatively. Bilirubin and biliary lipid levels in bile fell shortly before they increased in the serum. The results suggest that both obstructive and parenchymal factors are operative in infants with biliary atresia.

7433 THE DIAGNOSTIC VALUE OF SOME SERUM ENZYMES IN LIVER DISEASE.

(Eng.) Straub, J. P. (Dept. Internal Medicine, Free Univ. Hosp., Amsterdam, Netherlands). *Neth. J. Med.* 18(6):273-278; 1975.

The activities of several serum enzymes were determined in 121 patients with diseases of the liver and bile duct system in order to ascertain their diagnostic value. The enzymes studied included isocitrate dehydrogenase (ICDH), glutamate dehydrogenase (GDH), cholinesterase (CE), SGOT, SGPT, LDH, and alkaline phosphatase (AP). Three patient groups were identified: those with parenchymal damage of the liver (32 acute hepatitis, 15 chronic aggressive or persistent hepatitis, and 18 cirrhosis), 24 with extrahepatic biliary obstruction without evidence of metastases, and 32 with proved liver metastases. The contribution of enzyme determination to the differential diagnosis of liver disease was found to be comparatively small. The mean enzyme-activity values confirmed published results, but there was a considerable overlap of individual results in most groups, and any meaningful statistical analysis was precluded. Combinations of determinations were sometimes useful. A low CE activity with increased LDH activity pointed to malignant disease of the liver. The ICDH level was of little value when SGPT was also determined. In most cases of liver metastases, the SGOT:SGPT ratio was not greater than 1 (contrary to general opinion), and the (SGOT + SGPT):GDH ratio did not discriminate between the acute and chronic forms of liver disease. None of the enzyme activities differentiated between cirrhosis and chronic hepatitis.

7434 ANTIBODIES TO Escherichia coli IN CHRONIC LIVER DISEASES.

(Eng.) Simjee, A. E.; Hamilton-Miller, J. M. T.; Thomas, H. C.; Brumfitt, W.; Sherlock, S. (King Edward VIIIth Hosp., Natal, South Africa). *Gut* 16(11):871-875; 1975.

Individual antibodies to a large group of specific *Escherichia coli* O serotypes were sought in 12 patients with chronic active hepatitis, 6 patients with alcoholic cirrhosis, 9 patients with primary biliary cirrhosis, 8 patients with cryptogenic cirrhosis, 8 patients with portacaval shunt, and 9 normal controls. In addition, the immunoglobulin class of the antibodies was investigated to determine whether these antibodies contribute to the altered immunoglobulin concentrations found in patients with liver disease. The patients with chronic active hepatitis and those with alcoholic cirrhosis had a greater number of specific *E. coli* antibodies than did any of the other groups separately. One patient with chronic active hepatitis had 35 of 150 positive reactions, and one patient with alcoholic cirrhosis had over 25 positive reactions; in contrast, the number of positive reactions in the other groups did not exceed 10 in any patient. There was no correlation between the number of antibodies and the levels of immunoglobulins, either individually (IgG, IgA, or IgM) or in sum. In three of the patients in whom antibodies to a large number of serotypes were found, immunoglobulin classification was attempted by means of 2-mercaptoethanol treatment of the serum. The antibodies in these patients were predominantly of the IgM class, while the elevation of globulin in general was mainly due to increased IgG and IgA levels. Antibodies to *E. coli*, therefore, probably contribute only a small part of the increased globulin levels found in patients with chronic liver disease.

7435 THE HEMODYNAMICS OF DIFFUSE LIVER DISEASES.

(Eng.) Viamonte, M., Jr.; LePage, J. R.; Russell, E.; Roen, S. A.; Pereiras, R.; Zeppa, R.; Viamonte, M. (Dept. Radiology, Univ. Miami Sch. Medicine, Miami, FL 33136). *Semin. Roentgenol.* 10(3):187-196; 1975.

The effects of various liver diseases on the hemodynamics of the liver are reviewed. Two inflow tracts (the hepatic artery and the portal vein) and three outflow tracts (the hepatic veins, the biliary ducts, and the lymphatics) serve the liver in circulating blood, lymph, and bile. Cirrhosis of the liver is the pathologic end result of various noxious agents that affect that organ. Often in cirrhosis, there is an increase in the ratio of arterial to venous inflow resulting from various factors. Unduly frequent communication is seen between the portal and hepatic veins. Gastrointestinal hemorrhage is the most common complication and cause of death in hepatic cirrhosis with portal hypertension. It must be treated according to the activity and severity of liver damage and to the type and severity of the altered hemodynamics. Techniques for assessing the hepatic vascular physiology include wedged hepatic vein and free hepatic vein manometry, wedged hepatic venography, manometry along the inferior vena cava, and selective left renal venography, all of which can be performed consecutively. Selective splenic and hepatic arteriography also provide useful information. In patients with active bleeding, selective arterial infusion of vasopressin, or embolization of the supplying artery or the veins in the gastroesophageal region may help in stopping the bleeding.

7436 FIBROSIS IN CHRONIC LIVER DISEASE. (Eng.)

Popper, H.; Kent, G. (No affiliation given). *Clin. Gastroenterol.* 4(2):315-322; 1975.

The pathogenesis, diagnosis, and therapy of hepatic fibrosis are reviewed. The pattern of fibrosis is important in classifying cirrhosis and in differentiating it from chronic hepatitis and noncirrhotic hepatic fibrosis. The pathological picture of fibrosis characteristic for cirrhosis is described, as is that characteristic for chronic hepatitis and several noncirrhotic fibrotic conditions: hepatoportal sclerosis, congenital fibrosis, hepatic fibrosis with portal hypertension on an infectious basis, granulomatosis, and precirrhotic stages of portal fibrosis. The development of normal hepatic connective tissue is briefly reviewed, and the morphogenesis of several types of hepatic fibrosis is discussed. Fibrosis may result from parenchymal collapse, either bridging collapse or massive collapse. Active parenchymal fibroplasia may occur around damaged hepatocytes, proliferated bile ductules, capillaries, and macrophages containing phagocytosed material. Septa may be active or passive. Sustained injury of the hepatocytes is the most common event stimulating fibrosis. Phases of fibroplasia include the commitment of the cells to fibroplasia, formation of intracellular collagen, and extracellular maturation and deposition of collagen. The biochemical breakdown of connective tissue is discussed. Rational therapy for established hepatic fibrosis does not exist, and therapeutic measures are aimed rather at prevention. Anti-inflammatory therapy has been the most effective, but it is still only symptomatic.

7437 LIVER FUNCTION IN SURVIVORS OF THE ATOMIC BOMB. (Eng.)

Gregory, P. B.; Amamoto, K.; Archer, P. G.; Rickert, E. R.; Omori, Y.; Bizzozero, O. J., Jr.; Hamilton, H. B.; Johnson, K. G. (Atomic Bomb Casualty Commission, Hijiyama Park, Hiroshima, Japan). *Radiat. Res.* 63(3):578-583; 1975.

Screening liver function tests were obtained from 1,128 male and 1,867 female atomic bomb survivors and from matched, nonexposed controls. A total of 234 subjects (7.8%) had one or more test results greater than two standard deviations from the mean. Among these patients, the deviate test result was the cephalin-cholesterol flocculation test in 121 subjects, the alkaline phosphatase test in 53 subjects, the SGPT test in 36 subjects, and multiple tests in 24 subjects. When atomic bomb exposure on an age-, sex-, and city-specific basis, using distance from the hypocenter and reported presence or absence of acute radiation symptoms at the time of the bombing as the criteria for exposure, was correlated with each of the three liver function tests separately, as well as for all three tests combined, no detectable influence of exposure to ionizing radiation on the test results was found. Follow-up examinations of 172 of the 234 subjects with liver function test values greater than two standard deviations from the mean were conducted 2 months after initial testing, and diagnoses of hepatobiliary disease were equally divided among exposed and nonexposed subjects. Exposure to the atomic bomb does not appear to have resulted in long-term susceptibility to hepatic disease.

7438 ASPARTYLGLUCOSAMINURIA: UNIQUE BIOCHEMICAL AND ULTRASTRUCTURAL CHARACTERISTICS. (Eng.)

Isenberg, J. N.; Sharp, H. L. (Univ. California, Los Angeles, Sch. Medicine, Los Angeles, CA). *Hum. Pathol.* 7(4):469-481; 1976.

The case report and the biochemical and ultrastructural findings of the first diagnosed case of aspartylglucosaminuria in the United States are presented. The patient, a 2-yr-old girl, was first examined because of hepatosplenomegaly, mitral insufficiency, and mild psychomotor retardation. She had coarse facial features, an umbilical defect, and elastic joints. Roentgenograms demonstrated cortical thinning and an increased trabecular pattern in the long bones. No ophthalmologic abnormalities were present. Peripheral blood and bone marrow examinations showed vacuolated lymphocytes containing material that did not stain with Best-carmine or PAS reagents. Electron microscopy revealed enlarged lysosomes containing a fine granular matrix, suggesting a glycoprotein storage disease. Examination of the urine excluded mucopolysaccharidosis as a diagnosis. When the patient's urine and aspartylglucosamine (AADG) were analyzed together chromatographically, only a single spot was noted. When lysosomal hydrolase activities were compared in WBC homogenates from the patient and from controls, the mean level of AADGase activity in the homogenates of the controls was 8.1 nmol/hr/mg protein, while there was no net release of hexosamine in the patient. The level of N-acetyl-β-glucosaminidase in the patient (4,702.9 nmol/hr/mg) was elevated in comparison to that in controls (2,682.1 nmol/hr/mg), while the levels of α-L-fucosidase, α-mannosidase, and β-galactosidase in the patient were in the upper part of the control range. The ultrastructural findings in this patient differed from other reported cases of aspartylglucosaminuria in that no abnormalities were found in the endoplasmic reticulum, Golgi apparatus, or glycogen content of the liver.

7439 DIFFERENTIATION OF BILIARY ATRESIA FROM NEONATAL HEPATITIS BY ROUTINE CLINICAL EXAMINATIONS. (Eng.)

Chiba, T.; Kasai, M. (Second Dept. Surgery, Tohoku Univ. Sch. Medicine, Sendai, Japan). *Tohoku J. Exp. Med.* 115(4):327-335; 1975.

The differential diagnosis of neonatal hepatitis (33 patients), and congenital biliary atresia (90 patients) was studied on the basis of routine clinical examinations. The diagnosis of neonatal hepatitis was confirmed by surgical exploration, liver biopsy, and/or clinical examinations. Total serum cholesterol ranged from 150 to 350 mg/100 ml in almost all cases of neonatal hepatitis, compared to values of more than 350 mg/100 ml in 30% of patients with biliary atresia. There was no case of neonatal hepatitis in which serum phospholipids rose over 350 mg/100 ml, compared to several cases of biliary atresia with values over this limit. Cases with more than 19% relative content of α-globulin in total serum protein were indicative of biliary atresia, while those with less than 10% α-globulin suggested neonatal hepatitis. Many cases of neonatal hepatitis showed more than 10% γ-globulin, compared to values lower than 10% in biliary atresia. Cases of biliary atresia usually showed total serum bilirubin values over 10 mg/100 ml, but these values were below 10 mg/100 ml in one-half the cases of neonatal hepatitis. All patients with neonatal hepatitis had serum alkaline phosphatase values below 25 King-Armstrong U, while most patients with biliary atresia showed values over this limit. It was stressed that the differentiation between the two diseases be made as early in life as possible, since the most favorable therapeutic results with congenital biliary atresia are obtained before 10 weeks of age.

7440 ROLE OF LIVER SCANNING IN THE DIAGNOSIS OF HEPATIC METASTASES.

(Eng.) Hatfield, P. M. (Lahey Clinic Foundation, 605 Commonwealth Ave., Boston, MA 02215). *Med. Clin. North Am.* 59(2):247-276; 1975.

The role of liver scanning in the diagnosis of hepatic metastases is discussed in light of experience with 90 patients. Most often, scanning was done to determine metastases not clinically proven, to evaluate known metastases, to explain abnormal liver chemistries in the absence of an enlarged liver, to evaluate an enlarged liver in the absence of malignancy and cirrhosis, and to rule out causes other than cirrhosis for hepatomegaly or abnormal liver chemistries in suspected cirrhosis cases. Scanning was 79% accurate in differentiating benign liver conditions from hepatic neoplasms in 48 proved cases and 89% accurate when unproved cases were included. Subsequently proved hepatic metastases were demonstrated by scanning in 20% of 30 patients with unexplained hepatomegaly and no known malignancy, in 3% of 32 patients with abnormal liver chemistries and a liver of normal size, and in 4% of 28 patients with a clinical diagnosis of cirrhosis. Among 29 patients with subsequently proved metastases and normal liver function tests, 15% were shown by scanning. In only 1/29 was a normal scan associated with proved metastases. Although scanning is more specific than any combination of currently available liver function tests, a high false-positive response rate (10/39 in this series) is a distinct disadvantage. The false-positive rate was reduced to 17% when the 19 truly positive scans for liver metastases in those patients with known liver metastases were included and to 13% when the 22 unproved patients with a scan diagnosis of hepatic metastases were included.

7441 SUBTRACTION SCANNING OF LIVER METASTASES WITH ^{67}Ga and ^{99m}Tc.

(Eng.) Erjavec, M.; Movrin, T.; Snajder, J. (Inst. Oncology, 4 Vrazov trg, 61000 Ljubljana, Yugoslavia). *J. Nucl. Biol. Med.* 19(2):53-57; 1975.

A method of subtraction scanning using an off-line, computer assisted, dual-analyzer scintigraphic method is described. ^{99m}Tc colloid was used to label the liver tissue and ^{67}Ga citrate was used to label both liver and neoplasm. Subtraction of simultaneously recorded counts gave positive images over structures concentrating more gallium than colloid. Conventional liver scintigrams with radiocolloids indicated the correct condition of the liver in 53/86 cases. There were 8/44 false positives, 8/42 false negatives, and in 17 the scintigram was equivocal. The subtraction image allowed a correct assessment in 85/94 cases. There were four false negatives: two cases of large metastases (malignant neurinoma and colon adenocarcinoma), one case of metastatic breast carcinoma of $\sim$1 cm subsequently revealed at surgery, and one case of metastasis of a breast carcinoma involving the left lobe erroneously considered "normal median radioactivity." Six false positives included three cases of a slightly positive image probably due to statistical variation; two cases of positive small islands over the lower part of the liver, probably due to ill-cleansed bowels; and one case of Hodgkin's disease with a clearly positive subtraction image but negative findings upon laparoscopy. The latter may well have been a false-negative laparoscopy rather tha a false-positive scan. A relatively slight uptake of ^{67}Ga was found in six cases (two rectal, two breast, one gastric, and one lung carcinoma), but subtraction scanning afforded the correct diagnosis. The most impressive images were observed in cases of malignant lymphomas and other fast-growing tumors. In nine cases, the subtraction image defined disease located in the liver area (celiac, portal, and perisplenic nodes), but outside the liver itself. The advantages of this technique over conventional liver scanning are discussed.

7442 DEMONSTRATION OF GROWING CASTS OF HEPATOCELLULAR CARCINOMA IN THE PORTAL VEIN BY CELIAC ANGIOGRAPHY: THE THREAD AND STREAKS SIGN.

(Eng.) Okuda, K.; Musha, H.; Yoshida, T.; Kanda, Y.; Yamazaki, T.; Jinnouchi, S.; Moriyama, M.; Kawaguchi, S.; Kubo, Y.; Shimokawa, Y.; Kojiro, M.; Kuratomi, S.; Sakamoto, K.; Nakashima, T. (First Dept. Medicine, Chiba Univ. Hosp., Chiba 280. Japan). *Radiology* 117 (2):303-309; 1975.

Of 112 patients with hepatocellular carcinoma examined by selective celiac and hepatic angiography, 28 demonstrated regurgitation of the contrast medium into one of the large portal branches. Visualization of small intrahepatic portal branches was more frequently observed, and in nine, the "thread and streaks" sign, suggestive of tumor casts, was seen. This sign appeared shortly after the start of the injection and was most clearly seen at 3-3.5 sec. In four, the cast appeared to fill the entire length of the right portal vein, and in the other five, the cast was limited to a short distance in one of the major portal branches.

The majority of these patients had clinical signs of portal hypertension. The tumor cast was confirmed by autopsy in five of the nine. Among 115 autopsies for hepatocellular carcinoma, visible tumor growth in the large portal branches was observed in 83. Radiography of the excised livers disclosed that the contrast medium injected into the hepatic artery entered the tumor cast and ran hepatofugally to meet the portal blood near the hilus. Four cases are summarized, and several illustrative angiograms are included. The clinical significance of the "thread and streaks" sign is that the lobe containing a tumor cast in its major portal branch is supplied solely by the hepatic artery. If the right portal branch is involved, portal hypertension is inevitable, often leading to fatal complications.

7443 PRIMARY LIVER CARCINOMA—CLINICAL PICTURE AND DIAGNOSTIC POSSIBILITIES. A REVIEW OF SEVENTY-FIVE CASES. (Eng.) Kordac, V.; Kalab, M. (1st Medical Dept., Faculty General Medicine, Charles Univ., Unemocnice 2, 128 08 Prague, Czechoslovakia). *Acta Hepatogastroenterol. (Stuttg.)* 23(3):186-193; 1976.

The clinical findings in 75 patients (65 men) with pirmary liver carcinoma (PLC) are presented. The diagnosis was established in most patients during the sixth decade of life; the average age at death was 59.6 yr. A history of alcoholism was found in 19.4% of the patients, of smoking in 41.1%, of acute viral hepatitis in 21.3%, of porphyria cutanea tarda (symptomatic liver porphyria) in 16.0%, and of diabetes mellitus in 16.0%. PLC was associated wiht cirrhosis in 88.6% of the cases. The percentage of PLC cases associated with cirrhosis during 1951-1963 was lower than during 1963-1975. Most patients died 24 weeks (range 7-65 weeks) following the appearance of the first symptoms: pain, hepatomegaly, palpable tumor, weight loss, and fever. The correct diagnosis was made by laparoscopy in 25% of the 30 patients in whom it was performed. Liver biopsy, performed in conjunction with the laparoscopy in 15 of these patients, resulted in the correct diagnosis in 50%. Percutaneous liver biopsy alone facilitated the correct diagnosis in only 16.7% of 16 patients. Scintigraphic techniques and roentgenographic examination contributed toward the diagnosis in 31% and 36% of patients, resp. High alpha$_1$-fetoprotein levels (>3000 ng/ml) were found in the sera of 10 of 18 patients with PLC and cirrhosis. The most frequent cause of death in the 75 patients was liver coma (41.4%), and a further 8.0% of the patients died in liver coma following bleeding from esophageal varices. Bleeding from esophageal varices alone was the cause of death in 13.3% of the patients, and 21.3% died from Kachexia tumorosa. Of the 75 patients, 61.3% had no extrahepatic mestastases. Overall, agreement of clinical diagnosis and pathologic-anatomical diagnosis was found in 70.6% of the cases.

7444 TREATMENT OF PRIMARY LIVER CARCINOMA. (Eng.) Plengvanit, U.; Viranuvatti, V.; Chearanai, O. (Dept. Medicine, Siriraj Hosp., Mahidol Univ., Bangkok, Thailand). *Med. Chir. Dig.* 3(5):301-306; 1975.

The results of various methods of treatment were studied in 291 patients with primary liver cancer with or without cirrhosis. Of 109 patients treated by systemic chemotherapy with NH_2 and prednisolone, 73 also had cirrhosis. The carcinoma cell type was hepatoma in 89, cholangioma in 16, and undifferentiated in 4. Marked alleviation or disappearance of pain was seen after therapy in 65 of 103 patients (64%). A post-treatment reduction in size of the tumor was seen in 20%, and a reduction in consistency of the tumor was seen in 18%; in 19%, both parameters were reduced. Among the 103 patients, 26 patients (24%) experienced a 2-month remission of disease. Intra-arterial chemotherapy with NH_2 and prednisolone was used to treat 60 patients, of whom 32 had cirrhosis. The carcinoma cell type was hepatoma in 47, cholangioma in 4, and undifferentiated in 9 patients. Of 52 patients with pain before treatment, 38 (73%) had marked alleviation or disappearance of symptoms after therapy. Tumor size was reduced in 18 patients (30%), tumor consistency was reduced in 21 (35%), and both were reduced in 11 patients (18%). Of these 60 patients, 28 (47%) had a 2-month remission. Radiotherapy was used to treat 32 patients, of whom 25 had cirrhosis. Of these, 29 had hepatoma and 3 had cholangioma. The pain was alleviated or disappeared in 12 (40%) of 30 cases. A reduction in tumor size was seen in 15 cases (47%), in tumor consistency in 11 (35%), and in both, in 7 (22%). Of these 32 patients, 9 (28%) experienced a 2-month remission. Hepatic artery ligation was performed in 90 patients, of whom 23 had cirrhosis. There was an operative mortality of 10%. The diagnosis was hepatoma in 59, cholangioma in 24 and undifferentiated cell carcinoma in 7. Pain was alleviated or disappeared in 40 of 82 cases (50%) after surgery. Tumor size and tumor consistency were each reduced in 17 patients (19%) and both were reduced in 16 (18%). Of these patients, 31 (35%) had a 2-month remission. The results of treatment cannot be compared since the associated cirrhosis was different in each group.

7445 HEPATOCELLULAR CARCINOMA: A CLINICAL STUDY. (Eng.) Kirkpatrick, P. M., Jr.; Webster, P. D., III. (Dept. Medicine, Medical Coll. Georgia, Augusta, GA). *South. Med. J.* 68(12):1489-1493; 1975.

The clinical course of 40 patients (8 months to 85 yr, men outnumbering women by a 3:1 ratio) with histologically proved hepatocellular carcinoma was reviewed. Cirrhosis was present in 17/25 patients in which there was sufficient tissue in the biopsy specimen to make a determination. Symptoms (notably, abdominal pain, swelling, and mass) were present for an average of 4.8 months before diagnosis was established. Hepatomegaly, abdominal mass, weight loss, tenderness in the right upper quadrant, fever, and ascites were common physical findings upon admission to the hospital. The average hemoglobin and hematocrit values were 12.5 g/100 ml and 30%, resp. The WBC count on admission was greater than 12,000/mm^3 in eight patients. The serum alkaline phosphatase level was elevated in 30 patients, and SGOT level was elevated in 26. BSP excretion was delayed in 32 of the patients. A liver scan performed in 25 patients was abnormal in all instances. Determination of BSP excretion and alkaline phosphatase levels and the liver scan were the most useful diagnostic tests. The prothrombin time and bilirubin levels were normal or slightly elevated. Surgical exploration was done in 10 of the cases, but resection was attempted in only 2. Only four patients were alive 6 months after admission.

7446 HEPATOCYTIC HAMARTOMA (FOCAL NODULAR HYPERPLASIA OF THE LIVER): ANGIOGRAPHIC ASPECTS. (Eng.) Piffaretti, P. G.; Mosimann, R.; Roffi, V.; Chapuis, G. (Via Losanna 5, CH-6900 Lugano, Switzerland). *Radiol. Clin. Biol.* 45(1):1-8; 1976.

The case of a 24-yr-old woman with hepatocytic hamartoma is presented, and the angiographic findings are emphasized. The patient presented with right upper quadrant pain, and a firm ovoid mass was palpated under the right costal margin. An angiographic study demonstrated dilatation of the common hepatic artery, compared to the gastroduodenal artery, and of the hepatic artery proper. After the lobar bifurcation, one of the branches of the right hepatic artery followed a curved course around the upper part of the mass, and its lumen narrowed abruptly. The mass was vascularized by branches from this artery. The tumor appeared dense and homogenous and lobulated. There were no arteriovenous shunts or vascular lakes. The radiological diagnosis was hepatic adenoma or focal nodular hyperplasia. An encapsulated, 6 x 5 x 4-cm mass was removed. Microscopically, the tumor was fibrotic, with bundles of biliary ducts and chronic inflammatory cell infiltrates. The angiographic features in this patient appear to be identical to those of hepatocytic adenoma and of several cases of focal nodular hyperplasia described in the literature.

7447 SIGNIFICANCE OF SERUM LIPOPROTEID-X (LP-X) DETERMINATION FOR THE DIAGNOSIS OF CHOLESTASIS IN CHRONIC LIVER DISEASES. (Eng.) Milewski, B.; Palynyczko, Z. (Klinika Gastroenterologii, ul. Goszczynskiego 1, 02-616, Warsaw, Poland). *Pol. Med. Sci. Hist. Bull.* 15/3(5/6):551-555; 1975.

The value of serum lipoproteid-X (LP-X) determination for the diagnosis of cholestasis was investigated in 179 patients who had various chronic liver diseases. Histological evidence of intrahepatic cholestasis was found in 20 patients, and in all of these, LP-X was present in the serum. Among the 159 patients without histological evidence of cholestasis, LP-X in the serum was demonstrated in only 2 cases (both with chronic active hepatitis). A comparison of the LP-X test with other biochemical tests revealed that LP-X is of greater diagnostic significance for intrahepatic cholestasis than the determination of serum alkaline phosphatase, gamma-glutamyltranspeptidase, leucinaminopeptidase, and cholesterol. It is concluded that LP-X is a specific and sensitive biochemical index of cholestasis.

7448 FAMILIAL BENIGN RECURRENT INTRAHEPATIC CHOLESTASIS: INTERRELATION WITH INTRAHEPATIC CHOLESTASIS OF PREGNANCY AND FROM ORAL CONTRACEPTIVES? (Eng.) De Pagter, A. G. F.; van Berge Henegouwen, G. P.; ten Bokkel Huinink, J. A.; Brandt, K.-H. (Burg. van Engelenweg 124, IJsselmuiden, Netherlands). *Gastroenterology* 71(2):202-207; 1976.

Benign recurrent intrahepatic cholestasis was found in three members of a single family, and probably in a fourth. The cases of these four patients are presented. Needle liver biopsy in patient A, a girl who since the age of 18 months had had eight episodes of obstructive jaundice, showed cholestasis, which was not accompanied by any other changes. A pure bilirubin stone was removed from the gallbladder, at which time a peroperative cholangiogram showed no abnormalities. A second needle biopsy taken when the patient was asymptomatic showed a normal histology. Patient B, the sister of patient A, had recurrent episodes of extreme restiveness, pruritus, and discolored stools during the first year of life; there was no manifest jaundice. Later, she developed episodes of obstructive jaundice, which often occurred during or after a virus infection. During three pruritic phases, the only sign of cholestasis was moderately increased alkaline phosphatase activity; extremely high serum bile acid levels were found. Patient C, the cousin of the father of patients A and B, had had episodes of pruritus and jaundice since she was 14 days old. Since her second year of life, she had had six phases of obstructive jaundice. A cholecystoduodenostomy was established, from which cholangitis resulted at least once. During pregnancy, the patient developed pruritus and right upper abdominal pain; the cholecystogram revealed a stone, and cholecystectomy was performed. The patient developed persistent jaundice by the second postoperative day. The jaundice disappeared after a drain had been left in the common bile duct for 8 months. When the jaundice recurred 3 yr later, needle biopsy revealed intrahepatic cholestasis. For approximately 42 months, the patient received 20 g of cholestyramine daily. Patient D, the brother of patient C, had one icteric episode at the age of 6 yr, but did not develop another episode of jaundice (obstructive) until age 30 yr, following an episode of tonsillitis. Cholecystography after normalization of liver functions revealed no abnormalities. Needle biopsy disclosed no abnormality other than cholestasis. A normal bile acid level was found after normalization of the liver functions. Among 10 other family members (all women), pruritus without jaundice occurred in pregnancy in 6, pruritus with jaundice during pregnancy in 2, and pruritus during the use of oral contraceptives in 2. A literature review revealed at least 57 cases of benign recurrent intrahepatic cholestasis since 1959, and a familial form was fairly common. There also seemed to be a relation to the intrahepatic cholestasis sometimes seen during pregnancy and during oral contraceptive use. The data of the family study suggest an inter-relation of the three types of intrahepatic cholestasis.

7449 BILE ACID GLUCURONIDES, II. ISOLATION AND IDENTIFICATION OF A CHENODEOXYCHOLIC ACID GLUCURONIDE FROM HUMAN PLASMA IN INTRAHEPATIC CHOLESTASIS. (Eng.) Back, P. (Medizinische Universitatsklinik, Hugstetter Strasse 55, D-7800 Freiburg, W. Germany). *Hoppe Seylers Z. Physiol. Chem.* 357(2):213-217; 1976.

A bile acid glucuronide from the plasma of a patient with chronic intrahepatic cholestasis was isolated and identified chemically. The identification was based on the thin-layer chromatographic properties of the peracetylated methyl ester of chenodeoxycholic acid glucuronate, which could be separated from the methyl-ester polyacetates of other bile acid glucuronates. The compound isolated from the plasma showed typical (according to mass spectrometry) fragments for the sugar and bile acid moiety. The relative intensities of the fragments at m/e 371 (41%) and m/e 317 (100%) obtained at a source temperature of 206 C corresponded closely to those of the synthetic methyl 7α-acetoxy-3α-*O*-(methyl-2,3,4-tri-*O*-acetyl-β-D-glucopyranosyluronate)-5β-cholan-24-oate, m/e 371 (41%) and m/e 317 (100%) observed at a source temperature of 227 C. From considerations of the steric accessibility and higher reactivity of the C-3-hydroxyl group for substitution reactions, it is concluded that the synthesized reference compound is a chenodeoxycholic acid-3-β-D-glucuronide.

7450 ACUTE LIVER DISEASE AND ENCEPHALOPATHY MIMICKING REYE SYNDROME: A REPORT OF THREE CASES. (Eng.) Gall, D. G.; Cutz, E.; McClung, H. J.; Greenberg, M. L. (Hosp. Sick Children, 555 University Ave., Toronto M5G 1X8, Ontario, Canada) *J. Pediatr.* 87(6, pt. 1):869-874; 1975.

Three cases are described in which the clinical presentation and initial laboratory investigations suggested Reye's syndrome but in which subsequent clinical and biochemical evolution of the illness differed from that of Reye's syndrome. The patients were a 6-yr-old boy, a 4-yr-old girl, and a 23-month-old boy. All patients had a recent uncomplicated upper respiratory infection for which they had been briefly treated with erythromycin, phenylephrine-hydrocodone, or tetracycline, resp. All were found unconscious; patients 1 and 2 were in stage III coma, and patient 3 was in stage II coma when they were hospitalized. Unusual findings for Reye's syndrome included: absence of vomiting prior to the onset of encephalopathy; the sudden onset of coma without preceding delirium; slow recovery of consciousness, with severe neurologic sequela occurring in two children; severe renal impairment; normal pre-beta fraction on lipoprotein electrophoresis; decreased levels of β-1-C globulin; and normal blood ammonia levels in patients 2 and 3. The light microscopic histologic changes in liver biopsies from these patients differed in many aspects from those described in Reye's syndrome. The main insult affected the centrilobular hepatocytes, which showed coagulative necrosis; in Reye's syndrome, there is small droplet fatty change without necrosis. Unlike Reye's syndrome, the fatty change was focal and confined to the injured hepatocytes surrounding the necrotic areas, suggesting a degenerative rather than a primary phenomenon. Histopathologic findings similar to Reye's syndrome were a lack of portal inflammation and a return to normal within a short time after the acute insult, which was shown by a follow up biopsy 4 months later in patient 1. In the first two patients, electron microscopy revealed a conspicuous absence of glycogen, which was accompanied by an increase in smooth endoplasmic reticulum. The mitochondria showed decreased numbers of cristae and dense bodies, and the matrix contained occasional dense floccular deposits. These biopsies were taken within the first 24 hr of admission, while that in patient 3 was taken 10 days later; the smooth endoplasmic reticulum was prominent in this patient, but glycogen particles were present. The mitochondria were normal, and this case probably represents the early stages of recovery. The authors believe that these patients had a previously unrecognized disorder with multiple organ involvement, including the brain, liver, kidneys, and possibly the pancreas.

7451 ACUTE LIPOGRANULOMATOUS HEPATITIS. (Eng.) Haber, I.; Buyssens, N. (Dept. Internal Medicine, Algemeen Ziekenhuis Middelheim, Antwerp, Belgium). *Tijdschr. Gastroenterol.* 18(2):85-99; 1975.

A case of massive epithelioid- and giant cell lipogranulomatosis of the liver, accompanied by an acute self-limited febrile hepatocellular jaundice, is reported. A second case of epithelioid and giant cell lipogranulomatosis (in viral hepatitis) is presented to illustrate possible pathogenetic mechanisms. The first patient, a 34-yr-old man with alcoholic liver damage, presented with fever, fatigue, diffuse muscle pain, tachycardia, dark urine, and discolored feces. Although the patient was icteric, there were no signs of alcoholic liver disease. A percutaneous liver biopsy revealed numerous lipogranulomas throughout the lobule, but never within the portal tracts. The larger lipogranulomas showed multinucleated giant cells with palisading of the nuclei, and all transition stages of swollen epithelioid cells to giant cells were present. The portal tracts showed a variable lymphocytic infiltrate. The patient's symptoms disappeared spontaneously in 1 week. A second liver biopsy 6 weeks later showed that the granulomas had disappeared. Some portal tracts showed minor lymphocytic infiltration, while others were normal. Groups of swollen Kupffer cells filled with brown pigment and local accumulations of lymphocytes and plasmocytes were present in the sinusoids. The hepatocytes showed a moderate diffuse steatosis. The diagnosis was minimal granulomatous hepatitis, characterized by the presence of isolated giant cells, moderate steatosis, and the sequelae of hepatocellular damage. The patient stopped drinking and remains in good health. This patient was unusual in that the lipogranulomas were large and numerous, contained giant cells, and were associated with clinical symptoms. The authors propose two possible explanations for this: granulomas, arising in any granulomatous hepatitis associated with fatty liver, might sometimes accumulate preferentially around fat vacuoles and become lipogranulomas or small lipogranulomas that often exist in a steatotic liver may become exceptionally large and florid in response to concommitant viral hepatitis. These hypotheses are supported by the existence of a second patient with lipogranulomatosis. Percutaneous liver biopsy in this patient, a 35-yr-old man with viral hepatitis and no history of alcoholism, revealed five granulomas centered around lipid vacuoles; they were composed of epithelioid cells that fused to form multinucleate giant cells. Inflammatory infiltrates composed of lymphcytes, plasmocytes, and other mononuclear cells occurred in portal tracts and in sinusoids. Massive epithelioid- and giant cell lipogranulomatosis of the liver accompanied by an acute self-limited febrile hepatocellular jaundice remains a rare clinopathological entity.

7452 PORTAL HYPERTENSION IN INFANTS AND CHILDREN WITH HISTIOCYTOSIS X.

(Eng.) Grosfeld, J. L.; Fitzgerald, J. F.; Wagner, V. M.; Newton, W. A.; Baehner, R. L. (James Whitcomb Riley Hosp. Children, 1100 W. Michigan St., Indianapolis, IN 46202). *Am. J. Surg.* 131(1):108-113; 1976.

The cases of three children with histiocytosis X in whom cirrhosis, portal hypertension, and bleeding varices developed despite a good response to chemotherapy are presented. In all patients, hepatosplenomegaly, jaundice, and ascites were seen clinically, and liver biopsy following treatment showed cirrhosis with wide interportal fibrous bands and fine septa dividing the parenchyma into pseudolobules. The first patient, a 13-month-old boy, was treated for disseminated histiocytosis with x-ray therapy (1,000 rads) and monthly cycles of prednisone, methotrexate, cyclophosphamide, and vinblastine sulfate. Persistent hepatosplenomegaly led to readmission at 25 months. Although there was no evidence of active histiocytosis, the liver biopsy showed cirrhosis, and the BSP retention was 9.5%/45 min. Two episodes of gastrointestinal bleeding and the development of ascites, esophageal varices, and portal hypertension led to laparotomy, at which time a 1.2-cm side-to-side portacaval shunt was performed. Liver biopsy at the time of surgery showed diffuse macronodular cirrhosis, with dense bands of collagenized connective tissue connecting portal spaces and prominent proliferation of bile ducts; the pattern was consistent with cirrhosis due to healed histiocytosis X. The child is asymptomatic at the age of 5 yr. The second patient, a 14-month-old girl, was treated for histiocytosis X with prednisone, 6-mercaptopurine, and methotrexate. She had six episodes of gastrointestinal bleeding by the age of 7 yr. At this time, esophageal varices, hepatosplenomegaly, a prothrombin time 50% of normal, a serum albumin level of 2.9 g/100 ml, and portal hypertension were seen. A mesocaval shunt was performed. The patient has remained asymptomatic for 2.5 yr, despite the persistence of splenomegaly. The third patient, a 2.5-yr-old boy, was initially treated with vasopressin, aminopterin, and irradiation (600 rads) to the pituitary area. Growth failure occurred over the next 3 yr, hepatomegaly persisted, and the bilirubin level was mildly elevated. He was then treated with methotrexate (1.25 mg/day, p.o.). Sixteen months later, he had jaundice, hepatosplenomegaly, and prolonged prothrombin time. The liver biopsy showed diffusely nodular periportal fibrosis consistent with cirrhosis. He subsequently developed gastrointestinal bleeding. Hepatosplenomegaly persisted, and the BSP retention was 28%. A central splenorenal shunt was performed, and the patient remained asymptomatic until the age of 20, when he died from metastatic hepatoma. Portosystemic shunt procedures effectively relieve the threat of potentially fatal variceal hemorrhage and improve the opportunity for long-term survival in children with cirrhosis and portal hypertension due to healed histiocytosis X.

7453 RADIOLOGIC APPROACH TO OBSTRUCTIVE JAUNDICE AND PANCREATIC DISEASE.

(Eng.) Hawkins, I. F.; MacGregor, A. M.; Freimanis, A. (Dept. Radiology, Univ. Florida Coll. Medicine, Gainesville, FL 32610). *Med. Clin. North Am.* 59(1): 121-143; 1975.

Current radiologic procedures to evaluate jaundice or suspected pancreatic disease are discussed with emphasis on their applicability and accuracy, and an outline of the radiologic work-up of such cases is presented. The chief use of the plain film is to detect cholelithiasis, gallstones in the biliary tree, and calcification of the liver. Barium studies of the upper gastrointestinal tract are used mainly to detect primary neoplasms and also dilatation of the common duct and gallbladder. There is no oral or i.v. contrast medium for visualization of the biliary tree in the presence of hepatocellular or sustained jaundice. Endoscopic pancreatocholangiography with the side-viewing fiber duodenoscope allows visualization and cannulation of Vater's ampulla. It cannot detect small pancreatic neoplasms that do not involve the major ducts. Hepatic clearance of radioiodinated rose bengal is useful in distinguishing obstructions from hepatocellular disease, and some series have been reported with 95% accuracy. Selenium-labeled methionine for pancreatic scanning seldom fails to demonstrate major abnormalities, but it is incapable of defining the etiology. The main applications of ultrasound in the diagnosis of jaundice are: evaluation of the gallbladder and bile ducts, diagnosis of neoplasms and other masses in the pancreas and its vicinity that obstruct the common or other bile ducts, and evaluation of the liver, especially for intrahepatic masses. Each of these applications is discussed. Direct cholangiography is sometimes useful when other tests have failed to demonstrate the cause of jaundice. Percutaneous transhepatic cholangiography is successful in most cases in which the bile ducts are dilated, but in only 20%-50% when the ducts are not dilated. Other techniques briefly discussed are jugular transvenous cholangiography, femoral and antecubital transvenous cholangiography, angiography, and operative and postoperative cholangiography.

7454 MORPHOLOGICAL CHARACTERISTICS OF NEONATAL OBSTRUCTIVE JAUNDICE.

(Eng.) Balazs, M.; Lukacs, V. F.; Denes, J. (Janos Korhaz, H-1125 Budapest, Hungary). *Acta Paediatr. Acad. Sci. Hung.* 16(2):127-134; 1975.

Liver biopsy material from patients with neonatal obstructive jaundice was studied by electron microscopy. In material from a 5-week-old infant with biliary atresia, bile precipitates destroyed cell organelles in the liver cell cytoplasm. In some areas, the bile canaliculi were unusually wide. Some microvilli were destroyed, and their lumen contained a highly electron-dense material. There was increasing mitochondrial damage with time. The Kupffer's cells were swollen and showed intensive phagocytosis; bile precipitates of variable density were seen within the Kupffer's cells cytoplasm. The lumen of the sinusoids of this patient was considerably narrowed, due partly to active phagocytosis by the Kupffer's cells and partly to herniated areas of the cytoplasm that were partially imbibed with bile. This indicates that, in addition to cholestasis, hypoxia plays an active part in the development of the serious liver cell changes in biliary atresia. In the inspissated bile syndrome, the liver cell structure was generally unchanged; the main change was damage of the bile canaliculi and ductule membranes. In functional obstruction associated with isoimmunization and Rh incompatibility, no change was seen in the fine structure of the hepatic parenchyma, but deposits were present in the cytoplasm. The bile canaliculi were dilated, and the membranes were severely destroyed. In functional obstruction associated with ABO-incompatibility, there was mitochondrial damage in the liver cells, and high-density deposits were observed. Kupffer's cells were enlarged, showing accumulations of highly electron-dense pigments and damaged mitochondria.

7455 POSTOPERATIVE JAUNDICE. (Eng.) Koff, R. S. (Hepatology Section, Veterans Admin. Hosp., Boston, MA 02130). *Med. Clin. North Am.* 59(4): 823-829; 1975.

The causes of postoperative jaundice are reviewed. In patients with preexisting hepatocellular disease, postoperative renal failure may result in pronounced hyperbilirubinemia. The stresses of fasting and surgery may exacerbate hereditary hyperbilirubinemias and other familial disorders of bilirubin metabolism. Several factors contribute to postoperative overproduction of bilirubin. Hemolysis may be associated with transfusion, chronic hemolytic states (such as sickle-cell anemia), a deficiency in glucose-6-phosphate dehydrogenase, severe infection, or open-heart surgery. Hematoma resorption and pulmonary embolism also result in overproduction of bilirubin. Several types of hepatocellular disease may contribute to postoperative jaundice. Hepatitis-like conditions encountered postoperatively include viral hepatitis, the postpump (extracorporeal circulation) sydrome, drug- and/or anesthetic-induced hepatitis, and impaired perfusions resulting from congestive heart failure, shock, or hypoxemia. Hepatocellular disorders resulting from intrahepatic cholestasis may also be contributing factors, and they include sepsis, drug-induced cholestasis, or postoperative cholestasis. Other causes of hepatocellular disease that can result in postoperative jaundice include fatty liver and/or cirrhosis after intestinal bypass surgery for morbid obesity, hepatic resection, and hepatic dysfunction following liver transplantation. Extrahepatic biliary tract obstruction after bile duct surgery can result in postoperative jaundice, and acute postoperative cholecystitis has been reported following nonbiliary tract surgery in rare instances. Postoperative pancreatitis resulting from trauma or interrupted blood supply can also cause obstruction of the biliary tree.

7456 IATROGENIC ACCIDENT IN THE TREATMENT OF PORPHYRIA CUTANEA TARDA WITH CHLOROQUINE (RESOCHIN). (Ger.) Goerz, G.; Kreig, Th.; Eichenauer, M. G. (Universitats-Hautklinik, Moorenstrasse 5, D-400 Dusseldorf, W. Germany). *Arch. Dermatol. Forsch.* 255(2):169-176; 1976.

A porphyrin crisis following erroneous administration of a 10-fold higher dose of resochin (RS) than prescribed to a patient with porphyria cutanea tarda (PCT) is described. A 64-yr-old man with a history of gastric resection for chronic ulcers and surgery for lip carcinoma (with postoperative radiation) was found to have PCT, based on urinary porphyria excretion (6,960 μg/l). Instead of initiating RS therapy with 125 mg (twice weekly), an initial 1,250 mg dose was given. Within 24 hr, there were acute symptoms of fever, nausea, hypertension, joint pain, tachycardia, and subjective feeling of malaise--a clinical picture resembling acute episodes of porphyria acuta intermitteus (PAI). Urinary porphyrin excretion rose threefold (to 20,000 μg/l) but, unlike PAI, porphyrin precursor excretion remained normal and the relative amounts of kopro-, penta-, hexa-, hepta-, and uro-metabolites did not change. After 3 days, the symptoms regressed and the correct RS regimen was resumed in 12 days without complication. It is believed that RS overdoses exert a nonspecific membrane effect (perhaps especially in mitochondria), inducing a continuous porphyrin excretion and ultimate exhaustion of the hepatic porphyrin pool.

Hyperbilirubinemic States

7480 FORMATION AND ELIMINATION OF BILIRUBIN.

(Eng.) Bissell, D. M. (Gastrointestinal Res. Unit, Univ. California, San Francisco, CA 94143). *Gastroenterology* 69(2):519-538; 1975.

Bilirubin metabolism, from heme uptake and degradation to bilirubin transport and its eventual secretion into bile, is reviewed along with forms of hyperbilirubinemia. Bilirubin is produced by catabolism of the heme of hemoglobin by the reticuloendothelial system and the parenchymal cells of the liver. The hepatic parenchymal cell is the site of bilirubin formation from exogenous and multiple endogenous forms of heme. Specific mechanisms for their degradation are unknown, but recent studies implicate the microsomal heme oxygenase (MHO) system in degradating the heme of cytochrome P-450. The breakdown of hemoglobin heme, also a function of hepatic parenchymal cells, may be mediated by the same or other mechanisms, such as coupled oxidation. Bilirubin is eliminated from the blood and enters into the bile by dissociation from plasma albumin, transfer into hepatic parenchymal cells, binding to intracellular proteins, conjugation, and secretion across the canalicular membrane. Investigations into hyperbilirubinemia have focused on familial hyperbilirubinemias (Gilbert's, Crigler-Najjar, Dubin-Johnson, and Rotor syndromes), in which the defect is likely to be single and steady-state conditions prevail. Caloric restriction, which increases the plasma concentration of bilirubin, and phenobarbital administration, which has a reverse effect, may alter the formation and excretion of bilirubin. Their sites of action in bilirubin metabolism are being studied.

7481 JAUNDICE IN INFANTS OF GREEK PARENTAGE: THE UNKNOWN FACTOR MAY BE ENVIRONMENTAL.

(Eng.) Drew, J. H.; Kitchen, W. H. (Mercy Maternity Hosp., Clarendon St., East Melbourne, Victoria, 3002, Australia). *J. Pediatr.* 89(2):248-252; 1976.

Studies were undertaken in a Greek community in Australia to determine if the increased incidence and severity of jaundice seen among infants in some areas of Greece is genetically determined. When the daily bilirubin levels in 43 Greek and 124 Australian infants were determined for 2 months and compared, there were no significant differences between the two groups. The mean maximum serum bilirubin levels were 7.91 mg/dl in the Greek infants and 7.61 mg/dl in the Australian infants, and these peaks were reached at 69.7 and 63.2 hr of age, resp. ($p=0.03$). Among 220 Australian and 887 Greek infants in a second series, the mean serum bilirubin levels were 7.34 mg/dl in the Greek infants and 6.79 mg/dl in the Australian infants at 48 hr of age, and 8.30 mg/dl in the Greek infants and 7.75 mg/dl in the Australian infants at 72 hr of age. The statistical comparisons of those infants with levels above 12 mg/dl, above 16 mg/dl, and above 20 mg/dl at 74 hr of age revealed no differences between the Greek and Australian infants. There were no significant differences between the Greek and Australian infants in capillary or cord blood hemoglobin concentrations or in reticulocyte counts. Fifty-one of 2,617 Greek infants in a third series required exchange transfusions during a 37-month period, which was similar to the number of Australian infants (365/18,102). Twenty of 305 Greek infants required phototherapy, compared to 264 of 9,482 non-Greek infants ($p<0.01$). There was a strikingly low frequency of Rhesus incompatibility (31.4%) and a high frequency of other major blood group incompatibilities (47.1%) among the Greek infants with severe jaundice, in comparison to the respective frequencies in the Australian infants (77.9 and 8.6%; $p<0.02$ in both cases). Information regarding the county of birth of 781 mothers and 77 fathers of Greek infants was obtained; individual serum bilirubin levels at 48 and 72 hr for each county of maternal and paternal birth were compared by a chi-square correlation, which showed no significant difference in any county. The results indicate that the high frequency of severe neonatal jaundice that has been demonstrated throughout Greece is not carried with those who immigrate. Future studies of this problem in Greece should concentrate on regional environment rather than upon genetic influences.

7482 URINARY PHOTOCATABOLITES OF BILIRUBIN IN JAUNDICED NEONATES.

(Eng.) Bajpai, P. C.; Srivastava, K. L.; Singh, B.; Krishna Murti, C. R.; Kapoor, C. L. (King George's Medical Coll., Lucknow, India). *Indian J. Med. Res.* 64(4):529-536; 1976.

To elucidate the mechanism of the toxicity of the photodegradation products of bilirubin, the pattern of urinary excretion of bilirubin metabolites was compared in eight nonicteric, untreated neonates; eight jaundiced, untreated neonates; eight jaundiced neonates who received phenobarbital (5 mg/kg); and eight jaundiced neonates who received continuous phototherapy. Catabolite excretion was increased in the neonates receiving phototherapy. *In vitro* photo-oxidized bilirubin resolved into seven spots on paper chromatography, but in the urine of jaundiced neonates subjected to phototherapy, 10 different metabolites were detected. The urine of the untreated nonicteric babies showed only 2-4 spots, whereas the urine of jaundiced untreated newborns or that of jaundiced babies treated with phototherapy showed only 3-5 spots. The results suggest that, in addition to the normal bilirubin degradation product by hepatocytes, jaundiced neonates receiving phototherapy excrete a number of photo-oxidation products of the bile pigment.

7483 DUBIN-JOHNSON'S SYNDROME. A ONE-FAMILY STUDY.

(Spa.) Ortega Negrin, S.; Fernandez Castellanos, G.; Vergara Dominguez, B.; Alvarez Alonso, M.; Garcia Reina, V.; Diaz, J. M. (Hospital "Pedro Borras," F y 29, Vedado, Habana, Cuba). *Rev. Cubana Pediatr.* 47(2):287-293; 1975.

7484 BENIGN CONJUGATED HYPERBILIRUBINEMIA WITH PIGMENT IN THE LIVER (DUBIN-JOHNSON'S SYNDROME). PART II. ACTIVE SCREENING OF SUBJECTS WITH PROTRACTED BSP TEST. (Slo.) Sosovec, V.; Ivicic, L.; Gaspar, I.; Lachova, B. (Vnutornę oddelenie, Nemocni s poliklinikou, Levoca, Czechoslovakia). *Cesk. Gastroenterol.* 29(8):517-526; 1975.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

7485 THE ROLE OF ENDOTOXIN IN LIVER INJURY. (Eng.) Nolan, J. P. (Dept. Medicine, State Univ. New York at Buffalo, Buffalo, NY). *Gastroenterology* 69(6):1346-1356; 1975.

The role of the endotoxins from intestinal bacteria in the hepatic and extrahepatic manifestations of certain liver diseases is reviewed. A synergism exists between endotoxic and other hepatotoxic factors, such as nutritional or choline deficiency, which interact and lead to the development of cirrhosis. Possible mechanisms that may contribute to hepatic sensitivity to gastrointestinal tract endotoxins include alteration of serum and tissue factors necessary for detoxification, increased intestinal absorption of endotoxin, and hormonal influences (protection with steroids, but enhanced susceptibility with estrogens). The inability of the normal liver to deal with the small amounts of lipopolysaccharide ordinarily presented to it may accentuate existing hepatic damage by allowing toxic endotoxin levels to develop in the liver tissue and by allowing endotoxin to enter the systemic circulation. Animal experiments have shown that endotoxicity can be modified by increasing resistance through the development of nonspecific tolerance or specific immunization; by decreasing gut absorption by oral nonabsorbable antibiotics, cholestyramine resin, or immunization; and by removing the circulating endotoxin through hemoperfusion with Dowex 1-X2 resin or activated charcoal.

7486 N-PROPYL-AJMALINE-INDUCED INTRAHEPATIC CHOLESTASIS. (Ger.) Buscher, H. P.; Talke, H.; Rademacher, H. P.; Gessner, U.; Oehlert, W.; Gerok, W. (Medizinische Universitatsklinik, 7800 Freiberg, Hugstetter Str. 55, W. Germany). *Dtsch. Med. Wochenschr.* 101(18):699-703; 1976.

Two case histories of N-propylajmaline (NPA) hepatotoxicity are detailed. A 42-yr-old man with no personal history of hepatobiliary problems received NPA for 3 weeks for management of ventricular extrasystoles. Within a week the patient became febrile, with onset of icterus and hepatomegaly. Liver biopsy revealed periportal field inflammation with lymphoplasma cell elements, but predominantly eosinophilic clusters in the ducts. The ductal epithelium was partially destroyed and surrounded by lymphohistiocytic and eosinophilic elements. There were intralobular nuclear polymorphism and dilated bile capillaries with thrombose Intralobular inflammation was slight. Diagnosis was marked florid eosinophilic cholangitis and cholangiolitis with prominent cholestasis and cholestatic hepatitis. The bilirubin, SGPT, SGOT, alkaline phosphatase, neutral fat, and cholesterol increased under tetracycline, but gradually normaliz under ampicillin. Cholinesterase and gamma-globulin were unaffected. The second case, a 34-yr-old woman with an unexceptional history was given NPA for extrasystole management followed within a week by gastrointestinal symptoms, pruritus, and icterus. There was no hepatomegaly, but liver histology resembled that described for the first case, except for the presence of fatty hepatocyte vacuolization (30%) and glycogen deposition associated with the nuclear polymorphism. Diagnosis was eosinophilic cholangitis and pericholangitis with extensive cholestasis, a glycogen pattern resembling diabetes mellitus, and fatty liver. Prednisone (50 mg) supplemental to 100 mg of doxycycline for 3 days elicited rapid improvement. Although steroid management was ameliorative in the second case, the therapeutic effect of ampicillin in the first case is questionable, since the leucine aminopeptidase, gamma-glutamyl transpeptidase, and alkaline phosphatase elevations probably normalized spontaneously. Both cases represent allergic-hyperergic drug trauma reactions.

7487 OXYPHENISATIN-INDUCED LIVER DISEASE. (Ger Lindner, H.; du Bosque, G.; Dammermann, R.; Kloppel, G.; Krause, D. (Medizinische Abteilung, Deutsches-Rotes-Kreuz-Krankenhaus, 2 Hamburg 13, Bei Schlump 84, Hamburg, W. Germany). *Dtsch. Med. Woche schr.* 100(49):2530-2535; 1975.

The little-known problem of laxative hepatitis (LH) and its recurrence is reconsidered. The clinical sample included 14 women patients with a 2- to 20-yr history of oxyphenisative (OPS) laxative abuse and symptomatic history of epigastric pain (between 2 months and 6 yr), fatigue, arthralgia, skin irritation, nausea, vomiting, and febrility. In the interval between hepatic crises, a reexposure dose of 10 mg OPS (triacetyldiphenolisatin) was given twice on 2 successive days. The clinical picture was multiple, uncharacteristic, and could only be identified as chronic or acute liver or gallbladder dis-

e. The spectrum from absent to greatly elevated
tivity and from periportal fibrosis to progressive
rotic cirrhosis was found in biochemical, immuno-
ologic, laparoscopic, and histological assays.
6 of 10 cases, immunofluorescence found diminished
ibody titer to nuclei and smooth muscle. All 14
ients reached normal laboratory levels and histo-
ically confirmed inactivity after interruption of
. During reexposure to OPS, the average GOT
el rose to 144 U/l, SGPT to 97 U/l, and glutamic
ydrogenase to 25 U/l. The bilirubin response is
ultative and icterus never an obligatory symptom.
is believed that OPS is resorbed in the intes-
es, metabolized in the liver, and in nonresorb-
e form, secreted in the bile. The metabolite,
ne or after protein binding, releases an aller-
reaction in the bile duct system.

38 GLUCOSE HOMEOSTASIS IN PATIENTS WITH PARACETAMOL-INDUCED LIVER DAMAGE [Ab-
act]. (Eng.) Record, C. O.; Chase, R. A.; Alber-
, K. G.; Williams, R. (King's Coll. Hosp., Lon-
, England). *Digestion* 12(4/6):341-342; 1975.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

94 HEPATITIS IN CLINICAL LABORATORIES 1973-74. (Eng.) Grist, N. R. (Ruchill Hosp., Glas-
G20 9NB, Scotland). *J. Clin. Pathol.* 29(6):480-
; 1976.

-yr survey (1970-1972) of the incidence of hepa-
is occurring in clinical laboratories was con-
ued in a simplified form. A questionnaire was
t to members of the Association of Clinical Path-
gists in 1975, for the period 1973-1974. Thirty-
cases of hepatitis were reported in 28 labora-
ies, and 14 of these cases were of hepatitis B.
is represented an average annual attack rate of
per 100,000. Clusters of hepatitis cases occurred
the following groups: science-biochemistry,
dical-morbid anatomy, and technician-hematology.
e average attack rates per 100,000 for these groups
re 308, 302, and 292, resp. None of the 32 cases
s fatal, and only seven patients required hospital-
ation. The results suggest that the risk of hepatitis to laboratory staff falls into place among other occupational risks that require surveillance and precautions.

7495 HEPATITIS Bs ANTIGEN AND LIVER CANCER: A POPULATION BASED STUDY IN KENYA. (Eng.) Bagshawe, A. F.; Gacengi, D. M.; Cameron, C. H.; Dorman, J.; Dane, D. S. (Dept. Medicine, Univ. Nairobi, Nairobi, Kenya). *Br. J. Cancer* 31(5):581-584; 1975.

The prevalence of hepatitis B antigenemia was determined in two geographically different areas (differing in altitude) where the incidence of primary liver cancer (PLC) is known to differ. Hepatitis B surface antigen (HBsAg) was detected by radioimmunoassay in 59 of the 1,833 samples from the population. Twenty-one positive samples (2.7%) were from a high altitude area, and 38 (3.6%), from the low altitude area. In a previous study, the high altitude area had a lower incidence of PLC than did the low altitude area, and the aflatoxin levels in food samples in the high altitude area were lower than those in the low altitude area. The results fail to demonstrate any significant difference in the prevalence of HBsAg in these two areas, suggesting that aflatoxin may be a major cause of PLC in Kenya.

7496 CAN VIRAL HEPATITIS BECOME CHRONIC UNDER THERAPY? (Ger.) Muller, R. (Abt. Gastroenterologie, Dept. Innere Medizin, Med. Hochschule Hannover, Karl Wiechert Allee 9, D-3000 Hannover, W. Germany). *Munch. Med. Wochenschr.* 118(21):679-681; 1976.

The evidence that clinically mild viral hepatitis B infection can be iatrogenically protracted, leading to persistence or elevation of the hepatitis B surface antigen (HBsAg) and chronic liver disease, is examined. The three available therapies include gamma-globulin (GGT), steroids, and cytostatics and immunosuppressives (CIT). With GGT, the use of HB-hyperimmunoglobulin shortly after exposure or in early incubation can mitigate infectivity but also arrest endogenous antibody formation such that the infection cannot be overcome. With steroid therapy, there is a suppression of RNA synthesis in lymph tissue, which elicits lymphocytolysis and, possibly, also an adverse effect on interferon. Factors responsible for chronicity in steroids are even more intensive in CIT. Extinction of antibody titers beyond measurable range are not uncommon. In hemodialysis, the disease becomes anicteric and subclinical, with HBsAg persistence in the vast majority of cases. Despite incompleteness of data and absence of effective statistics, there is no evidence that GGT, steroids, and CIT do not induce a switch from acute to chronic forms. It is even conceivable that immunological competence could be so attenuated that reinfection is possible.

7497 PREVENTION OF POST-TRANSFUSION HEPATITIS. ROLE OF SENSITIVE HEPATITIS B ANTIGEN SCREENING TESTS, SOURCE OF BLOOD AND VOLUME OF TRANSFUSION. (Eng.) Koretz, R. L.; Gitnick, G. L.; Mitchell, J. E.; Damus, K.; Ritman, S. G.; Golub, L.; Kash, P. L. (Div. Gastroenterology, Dept. Medicine, Center for Health Sciences, Univ. California, Los Angeles, CA 90024). *Am. J. Med.* 59(6):754-760; 1975.

The role of sensitive hepatitis B surface antigen (HBsAg) screening tests, the source of blood, and the volume of transfusion in the prevention of post-transfusion hepatitis (PTH) was investigated in 112 patients. Aliquots from units of blood were screened by radioimmunoassay (RIA) and reverse passive hemagglutination (RPHA) shortly after transfusion. Recipients of positive units (HBsAg recipients, 21; RIA false positives, 34; RIA indeterminant positives, 15) as well as control subjects (42) were followed prospectively for evidence of either PTH or exposure to hepatitis B (HB). The incidence of HB in the RPHA-positive (59%) and RIA-positive (53%) patients was significantly higher ($p<0.005$ and $p=0.005$, resp.) than in the control patients (17%). Similarly, the incidence of HB exposure was significantly higher in these two groups (76% and 67% versus 29%, $p<0.001$ and $p<0.01$, resp.). The incidence of non-HB was the same in the three groups. A total of 83% of the 1,045 U of blood given as transfusion to the 112 patients came from commercial blood banks. Of these, 21 U were positive, with 19 originating from commercial sources. Although there is a slightly higher proportion of positive units in the commercial compared to the voluntary sources in both groups, these differences are not significant ($p>0.10$). The overall incidence of PTH was higher in the recipients of all commercial blood (41% versus 0%, $p>0.05$). A major relation could not be demonstrated between an increased frequency of PTH and increasing amounts of transfused blood.

7498 IMMUNISATION AGAINST HEPATITIS B IN MAN. (Eng.) Maupas, P.; Coursaget, P.; Goudeau, A.; Drucker, J. (Institut de Virologie de Tours, 2 bis Boulevard Tonnelle, 37000 Tours, France). *Lancet* 1(7974):1367-1370; 1976.

An inactivated vaccine against hepatitis B was prepared from blood donor hepatitis B surface antigen (HBsAg) purified on immunoadsorbents. Of the 45 subjects who were vaccinated, 35 produced antibodies against HBsAg. A primary humoral response was noted in 28 subjects. Of the 39 subjects who had no serological marker of past hepatitis B infection, 28 had a primary humoral response and 4 had a cellular immune response, demonstrated by skin test with vaccinal HBsAg. In the 28 subjects with a hormonal response, anti-HBsAg was detected early in 11 cases. In the remaining 17 cases, anti-HBsAg appeared 2-3 months after the first injection. This pattern of anti-HBsAg production was similar to that noted in natural infection. After two injections separated by 1 month, 7 (18%) vaccinated subjects did not respond by specific, detectable signs of immunity. The fact that HBsAg antibodies are still present at protective levels 6 months after the first injection indicates that a yearly booster should suffice. In a hemodialysis unit, no vaccinated subject gave any sig of clinical or biological hepatitis, while during the same time period, 43% of nonvaccinated patients became HBsAg-positive. No significant differences in immunological responses were noted between dialyzed patients and ward staff. This vaccination may be the first instance of prevention of a potentially oncogenic viral infection, in that by specific vaccination against hepatitis B in areas of high endemicity for hepatitis-hepatoma, it might be possible to interrupt or even eradicate this process.

7499 HIGH-TITRE HEPATITIS B IMMUNE GLOBULIN. (Eng.) Anonymous (No affiliation given). *Br. Med. J.* 1(6004):241-242; 1976.

Recent studies concerning the use of immune-globulin-containing high titers of antibody to the hepatitis

surface antigen (HBsAg) for the prevention of hepa-
itis B virus infection among members of dialysis
nits and spouses of hepatitis patients are reviewed.
mong 251 persons who were exposed to hepatitis B
irus by accidently pricking a finger on a needle
ontaminated with blood from an HBsAg-positive pa-
ient, hepatitis developed within 6 months in 17
ho were immunized with a low-titer globulin; among
53 similarly exposed persons who were given the new
igh-titer globulin, only 5 developed hepatitis with-
n the same period. After a further 3-month follow-
p, six more cases had appeared, all in the group
iven the high-titer globin. One explanation might
e that the high-titer globulin may have completely
revented the development of active immunity; this
heory is supported by one study in which the fre-
uency of antibody to HBsAg rose progressively dur-
ng follow-up and at 6 months was significantly
igher in those receiving low-titer globulin than
n the high-titer group (32% and 7%, resp.). It
eems that repeated injections of hepatitis B immune
lobulin will be required if there is a likelihood
f further exposure, although the long-term hazards
f such an approach are unknown.

500 INCIDENCE OF VIRAL HEPATITIS AFTER ADMINISTRATION OF FACTOR IX CONCENTRATES.

Eng.) Iwarson, S.; Kjellman, H.; Teger-Nilsson,
. C. (Univ. Goteborg, East Hosp., Goteborg,
weden). *Vox Sang.* 31(2):136-140; 1976.

linical trials with the human factor IX concen-
rates, Konyne and Preconativ, were carried out to
etermine the incidence of clinical hepatitis,
hich has been frequently reported after treatment
ith Konyne. During the first 2 yr of the trial,
6 patients were treated with either one or both
reparations. Nine patients developed viral hepa-
itis within 6 months after treatment. During the
ext 4 yr, another 26 hemophiliacs were treated
ith Preconativ alone. Only two cases of hepa-
itis occurred. Selection of donors and screening
or hepatitis B surface antigen in donor blood used
or the manufacturing of Preconativ might be con-
ributing factors to this low hepatitis incidence.

501 CYTOPHOTOMETRIC STUDIES OF THE DNA, NUCLEIC ACID AND PROTEIN CONTENT OF LIVER CELL UCLEI FROM PATIENTS WITH VIRUS HEPATITIS. (Eng.)

anek, L. (Rigshospitalet, 9 Blegdamsvej, DK-2100
openhagen 0, Denmark). *Acta Pathol. Microbiol.*
cand. [*A*] 84(1):1-8; 1976.

o investigate the cause of the increased size of
epatocyte nuclei seen in viral hepatitis, the nuclear
ize and the nuclear contents of DNA, nucleic acid,
nd protein were measured by cytophotometry in 45
iver biopsies from patients with acute viral hepa-
itis and in control biopsies. Both control nuclei
nd nuclei from the patients were predominantly di-
loid. The average area of nuclei from hepatitis
atients (96 μm^2) was significantly greater than that
f the nuclei from the controls (79 μm^2, $p<0.001$).
he DNA content in both control nuclei and nuclei
rom the hepatitis patients was similar. UV spectrophotometry of 34 nuclei from two patients demonstrated an average nucleic acid content of 8 pg, whereas that in the controls was significantly lower (7 pg). There was also a positive correlation between nuclear size and nuclear protein content. The increased nuclear size seen in viral hepatitis is primarily due to a higher protein content, suggesting that the nuclear function is increased during the course of this disease.

7502 THE LACTATE DEHYDROGENASE ISOENZYMES IN VIRAL HEPATITIS. (Ger.) Eisenburg, J.;

Kellner, E.; Munte, A. (I. Med. Univ.-Klinik, Ziemssenstrasse 1, 8 Munchen 2, Munich, W. Germany). *Fortschr. Med.* 94(12):673-688; 1976.

The differential diagnostic and prognostic role of serum LDH isoenzymes in acute and chronic human viral hepatitis is examined. Agar gel electrophoresis was the method of choice for heterogenous LDH separation. An assay of 23 healthy control persons established five LDH isozyme patterns; there was no sex difference. In four patients, in the early healing phase after acute viral hepatitis (AVH), the total (in IU) LDH was 185, LDH_1 was 120, LDH_2 was 50, LDH_3 was 10, and LDH_4 and LDH_5 were negligible; GOT and GPT were less than 20 IU. Among 20 patients with acute viral hepatitis, there were 4 with LDH_5 levels over 100 IU, with a total LDH in excess of 400 U/1 and SGOT-SGPT elevations above 1,500 U/1. In seven cases of delayed healing, LDH_5 was 32-100 IU. In recurrences of acute viral hepatitis, GPT rose more rapidly to higher levels than did LDH_5. Nine patients with acute viral hepatitis had elevated transaminases, but normal LDH_5, during the first 3 weeks of the disease. In hepatitis with acute recurrences, the LDH_5, transaminase, and total LDH activity curves were parallel. There was no correspondence between enzymatic and histological diagnoses in nine patients with chronic viral hepatitis since the mesenchymal inflammation and epithelial lesions are not concomitant. In two cases where total LDH, SGOT-SGPT, and LDH_5 were increased concurrently, the LDH_1-LDH_4 fractions were unexceptional; in both patients, the GOT/GPT exceeded 2 IU and the prognosis was highly unfavorable. In general, discrepancies between SGPT and LDH_5 are more frequent in chronic viral hepatitis than in the acute form. LDH_5, total LDH, and transaminase levels changed little in chronic viral hepatitis or in incipient cirrhosis with negligible inflammation, in fatty liver, and in extrahepatic obstructive jaundice. In 18 patients with concurrent primary liver carcinoma and cirrhosis, the LDH_5 activity increased proportionately with the degree of hepatomegaly and disproportionately with total LDH activity. Total LDH was markedly elevated in preterminal progressive cirrhosis, especially after hunger dystrophy. The LDH isozyme patterns are too insensitive to find diagnostic use in chronic hepatitis; their value is restricted to hepatitic icterus and primary carcinoma in cirrhotic livers.

7503 SERUM LEVEL CHANGES OF ENDOGENOUS AND POST-HEPARIN DIAMINE OXIDASE (HISTAMINASE) IN CLINICAL AND EXPERIMENTAL HEPATITIS. (Eng.) Gang,

V.; Baldus, M.; Kadereit, M. (Medizinische Universitatsklinik, Josef-Schneider-Strasse 2, 87 Wurzburg, W. Germany). *Acta Hepatogastroenterol. (Stuttg.)* 23(2):104-109; 1976.

Serum level changes of endogenous and posthepatic diamine oxidase (DAO, histaminase) were investigated in 14 healthy volunteers, 12 patients with acute viral hepatitis, and in female Wistar rats. All human subjects received 200 U heparin/kg i.v. for DAO release. In the rats, galactosamine hepatitis was produced by 800 mg Gal-N/kg i.p., and the animals received 1,250 U heparin i.v. 6-72 hr later. Blood samples were taken from humans and animals up to 3 hr after heparin injection. The DAO levels in all the patients were significantly decreased (from 29.5 to 17.0 mU/l plasma), but the levels in the rats were increased (from 32.5 to 60.0 mU/l plasma). Some patients showed at the time of maximum DAO elevation (90 min), values below 10% of controls. The time course of postheparin diamine oxidase (PHD) was investigated in one hepatitis patient. With normalization of SGPT values, there was a tendency for PHD to increase, and an inverse correlation was found between the two. In the rats, a fivefold increase in DAO was observed 48-72 hr after Gal-N application. This increase was correlated significantly to the increase of PHD ($r=0.685$, $p<0.0005$, $n=54$). It is concluded that in the rats, increases in DAO levels were mediated by endogenous heparin, released from disrupted mast cells. In the hepatitis patients, the decreased endogenous and postheparin DAO levels would correspond to a depletion of the enzyme-containing organs.

7504 INFECTIOUS PARTICLES IN HEPATITIS. (Eng.)

Waterson, A. P. (Dept. Virology, Royal Postgraduate Medical Sch., Univ. London, Ducane Road, London, W. 12, England). *Annu. Rev. Med.* 27:23-35; 1976.

Information on the as yet unidentifiable, filterable agents responsible for most cases of acute hepatitis in men is reviewed. There are at least two known agents, hepatitis A and B. Hepatitis B can be identified in patients and carriers by finding the hepatitis B antigen (HBAg) in the blood. Hepatitis A has no corresponding antigen in the blood, but particles have been found in the feces of patients and experimentally infected human subjects. Hepatitis B boasts a DNA-containing particle, the Dane particle, which is linked to the clinical illness and resembles a conventional DNA virus. However, it does not share the exact morphology of any known virus. For hepatitis A, a particle that is identical in morphology with the enteroviruses has been described, but its relation to the illness has not been determined. Concerning hepatitis A, studies of its transmission to marmosets and the correlation with human infection, electron microscope studies on natural and artificial human infections, grounds for associating the 27-nm particle with this agent, and its relation to gastroenteritis viruses in man and other vertebrates are summarized. With respect to hepatitis B, the Dane particle, the antigenic makeup of HBAg, and the preparation of vaccines consisting of HBAg from which Dane particles have been removed are reviewed.

7505 SEROLOGICAL HEPATITIS-B CHARACTERISTICS IN CLINICAL LABORATORY CONTROL SERA. (Ger.)

Lehmann, H.; Bruhn, H. D.; Schlaak, M. (Abteilung Allgemeine Innere Medizin der Univ., 2300 Kiel, Schittenhelmstr. 12, W. Germany). *Dtsch. Med. Wochenschr.* 101(18):688-689; 1976.

The presence of hepatitis B surface antigen (HBsAg) and its antibody (anti-HBs) were assayed in various control sera from different sources. With countercurrent electrophoresis, all 99 serum samples were negative for HBsAg and anti-HBs. With radioimmunology, 4 of the 99 samples were HBsAg-positive and 45 were anti-HBs-positive; 50 had no HBs characteristics. Relative to the number of reference sera (29), 4 were HBsAg-positive, and 5 were anti-HBs-positive; 20 were without HBs involvement. The danger posed by HBsAg-positive reference sera is amplified, since they are used over a period of many weeks. Serum samples that are pooled for preparation of standard sera should be tested radioimmunologically for HBsAg and anti-HBs.

7506 HEPATITIS B SURFACE ANTIGEN AND HUMAN SERUM PROTEINS. (Eng.)

Schuurs, A. H. W. M.; Wolters, G. (Organon Scientific Development Group, Oss, Netherlands). *Am. J. Med. Sci.* 270(1):173-177; 1975.

The purification of hepatitis B surface antigen (HBsAg) is described and the presence of human serum proteins in the antigen was investigated. The purification involved digestion with pepsin preceded and followed by ultracentrifugation. Most often, two pepsin digestions were required to obtain preparations in which serum proteins could no longer be detected by immunodiffusion. Pepsin treatment did not seem to affect the subtypes *d* and *y*. It did not cause any appreciable loss of immunochemical HBsAg activity. Hyperimmunization of sheep with these preparations in complete Freund's adjuvant evoked high-titered anti-HBs sera that sometimes contained antibodies to serum proteins. These antibodies were removed easily by treatment of the antiserum with insolubilized human serum proteins. In another study, a sandwich technique was used to determine whether HBsAg binds to anti-normal human serum (NHS). Partially purified and highly purified HBsAg were tested in two dilutions in normal sheep serum and in tris-HCl buffer. The binding was monitored with enzyme-labeled sheep anti-HBs. There was little evidence of binding of HBsAg to the solid phase. Electron microscopy of highly purified HBsAg in the presence of anti-NHS did not reveal any clumping of particles, but this phenomenon was very pronounced in the presence of anti-HBs. It is concluded that the presence of human serum protein-like material in HBsAg is still a matter of controversy.

LIVER AND BILIARY TRACT

Chronic Hepatitis

7527 CHRONIC ACTIVE HEPATITIS IN CHILDHOOD. (Eng.) Tolentino, P. (Inst. Infectious Diseases, Univ. Genoa, Genoa, Italy). *Paediatrician* 5(1/2):67-73; 1976.

The classification of chronic active hepatitis (CAH), specifically, the form that follows hepatitis B virus infection in childhood, is discussed. Hepatitis B surface antigen (HBsAg)-positive CAH is characterized by a high level of serum immunoglobulins (Ig, especially IgG and IgM) in all cases, including pediatric ones. There is also an Ig deposit at the surface of the hepatocytes, as demonstrated by immunofluorescence. There is enhanced reactivity of the T lymphocytes, both aspecific (to phytohemagglutinin, PHA) and specific (to hepatic lipoproteins). The histological aspects of the liver show an aggressive periportal and lobular inflammation by lymphocytes, similar to that of transplantation rejection. An *in vitro* cytotoxicity for hepatocytes by lymphocytes from chronic hepatitis patients has been shown, along with an increased percentage of these lymphocytes without B- and T-cell markers. It is hypothesized that there is an increased number of killer cells destroying hepatocytes. Finally, the disease responds favorably to immunosuppressive therapy. These factors establish that HBsAg-positive CAH is a progressive, self-perpetuating autoimmune disease that is triggered by virus infection and whose chronic evolution is due to different virus- and host-dependent factors. Factors that initiate the chronic evolution of acute hepatitis B are distinct from those responsible for the self-perpetuating mechanism. As a consequence, corticosteroids have different effects. They are harmful in the acute stage, impairing the immune defenses and starting a chronic evolution, but they are very useful (along with azathioprine) in the chronic stage, when immunosuppressive therapy is needed.

7528 MORPHOLOGY OF ANICTERIC PEDIATRIC INFECTIOUS HEPATITIS. 1 COMPARATIVE HISTOLOGY OF LIVER PUNCTURES IN ICTERIC AND ANICTERIC VIRAL HEPATITIS. (Ger.) Wiegand, U.; Martin, H.; Gudowski, G.; Tacke, A.; Schneeweis, B. (Kinderklink, Bereich Medizin (Charite) Humboldt Univ., 104 Berlin, Schumannstr. 20/21, E. Germany). *Dtsch. Gesundheitsw.* 31(23):1075-1081; 1976.

Morphological differentiation in pediatric icteric and anicteric viral hepatitis (VH) are described. The clinical sample consisted of 113 punch biopsy specimens from 51 anicteric (group A) and 62 speciments from 26 icteric children (group B) with VH. The average age of the children was 6 yr (2-15 yr); infants were excluded. About 70% of both groups were Australia antigen positive. Single cell necrosis and mitosis were about equal in both groups up to 2 weeks after clinical onset, but diminished thereafter. Multinucleated cells increased in weeks 2 and 3. Inflammatory infiltration of periportal fields, which peaked during the 1st week, was found equally in both groups A and B throughout the observation period. Focal proliferation of astrocytes, whose extent remained constant through all phases, was obvious in 80% of all specimens in week 7; diffuse astrocyte proliferation peaked in week 1 and continued to regress to near extinction in week 5. A slight proliferation of collagenous connective tissue began in both groups A and B during week 1 and continued to increase; it was frank in more than 60% of all specimens by week 3. Parenchymal icterus, which peaked in group B during week 2, was associated with serum bilirubin levels below 2 mg/100 ml. Siderin was significantly higher ($p<0.01$) in one-third of group B and one-tenth of group A by weeks 3 and 4. Although there is little qualitative difference between groups A and B, quantitative distinctions begin to appear in week 2. The number of necroses and mitoses in group A was lower ($p<0.01$) than in group B.

he degree of diffuse astrocyte proliferation was
igher ($p<0.01$) and the inflammatory extent of peri-
ortal fields greater ($p<0.05$) in group B than in A.
ocal astrocyte proliferation was equal. These dif-
erences disappear after week 2. Histologically
anifest differentia are mainly confined to the
arenchymal phase of disease.

529 AUTOLYMPHOCYTOTOXINS (CoCoCy) IN PATIENTS
WITH DIFFERENT FORMS OF HEPATITIS AND CIR-
HOSIS. (Ger.) Bertrams, J.; Kuwert, E.; Selmair,
.; Reis, H. E.; Wiese, W. (Laboratorien des St.
lisabeth-Krankenhauses Moltkestr. 61, D-4300 Essen,
. Germany). *Klin. Wochenschr.* 54(5):227-233;
976.

era of 282 patients with different forms of hepa-
itis and cirrhosis were screened for cold-reacting
omplement-dependent autolymphocytotoxins (CoCoCy).
hese antibodies are 19S-immunoglobulin M and have
o HLA antigen specificity. The CoCoCy occurred in
he sera of 48% of the chronic aggressive hepatitis
atients, 14% of the chronic persistent hepatitis
atients, and in 30% and 45% of two groups with
cute hepatitis. No correlation was found between
oCoCy and hepatitis B antigen (HBAg). The CoCoCy
ould also be demonstrated in 20% of an HBAg-
ositive and in 6% of an HBAg-negative control
roup. The actual serum concentration of CoCoCy was
ow. They seemed to be T-cell specific and to re-
lect the overall immunoreactivity without relation
o the specificity of the antigenic stimulus. It
s concluded that CoCoCy may be of pathogeneic and
athodynamic rather than diagnostic interest.

530 THE SERUM TRANSFERRIN LEVEL IN CHRONIC
HEPATITIS CASES. (Ger.) Ohlenschlaeger,
.; Berger, I. (Gustav-Embden-Zentrum der Biologis-
hen Chemie, Frankfurt Untersuchungsstelle, Frank-
urt, W. Germany). *Fachz. Labor.* 19(12):1173-1175;
975.

he serum transferrin (ST) levels in four types of
hronic hepatitis are reported. The test group in-
luded 141 cases of active chronic hepatitis with
low progression, 18 cases with a more rapid
rogression, 116 cases of persistent chronic hepa-
itis, and 40 patients with chronic necrotizing
epatitis. Normal ST levels, with a mean of 255.99
g/100 ml, were found in 251 patients, and depressed
evels, with a mean of 165.23 mg/100 ml, were found
n 64 patients. The lowest value obtained was 130
g/100 ml, and only in one case of chronic persis-
ent hepatitis was ST as high as 425 mg/100 ml. No
tatistical correlation could be established between
T level and hepatitis type. The liver parenchyma
as sufficient transferrin synthesis potential in
epatitis.

531 EARLY RENAL IMPAIRMENT IN CHRONIC HEPATI-
TIS. (Eng.) Gentilini, P.; Laffi, G.;
uzzelli, G.; Stefani, P.; Masi, R. (Cattedra di Patologia Speciale Medica e Metodologia Clinica 2R, Universita di Firenze, 50134 Firenze, Italy). *Rend. Gastroenterol.* 7(3):194-196; 1975.

Renal function tests, including glomerular filtration rate (GFR) and renal plasma flow (RPF), were carried out in 34 patients with chronic active hepatitis, 19 patients with active cirrhosis, 13 patients with other chronic liver diseases with portal hypertension, and 12 patients with other chronic liver diseases without portal hypertension. A selective renal arteriography and a kidney scan with ^{99m}Tc-microspheres of human albumin were also performed in 24 patients. In 35.3% of the patients with chronic active hepatitis, there were changes in RPF. The GFR was abnormal in 38.2%. The RPF and GFR were abnormal in 57.9% and 47.3%, resp., of the patients with active cirrhosis. The RPF and GFR were abnormal in 53.8% and 69.2%, resp., of those with portal hypertension, and in 75% and 91.6%, resp., of those without portal hypertension. The kidney scan showed arteriovenous shunts opening in the kidneys in 3 of 8 patients with chronic active hepatitis, in 6 of 10 patients with active cirrhosis, and in 2 of 5 patients with portal hypertension. The kidney scan was normal in the one patient without portal hypertension in whom it was carried out. The results show early renal function changes in patients with chronic active hepatitis before the onset of clinical and functional signs of cirrhosis and before water retention or increase in the levels of creatinine and blood urea nitrogen occur.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

7537 DEOXYCHOLATE METABOLISM IN ALCOHOLIC CIRRHOSIS. (Eng.) Knodell, R. G.; Kinsey, M. D.; Boedeker, E. C.; Collin, D. P. (Univ. New Mexico, Sch. Medicine, Albuquerque, NM 87131). *Gastroenterology* 71(2):196-201; 1976.

Studies were carried out in six patients with alcoholic cirrhosis and in controls to determine the mechanism responsible for the absence of deoxycholate in the bile of cirrhotic patients. Four cirrhotic patients had no detectable deoxycholate in the bile, while the deoxycholate levels in the other two patients were 3.3 and 14.1% of the total bile acids, resp. The mean fecal excretion of ^{14}C-deoxycholate (36.3% excreted) and the calculated deoxycholate fractional turnover constants (0.102 days) and half-lives (8.7 days) in the cirrhotics were not significatly different from those of three controls; these values were similar in the cirrhotics with and without deoxycholate in the bile. A trend toward decreased ^{14}C-deoxycholate fecal excretion with decreased fractional turnover and prolonged deoxycholate half-life was seen in the cirrhotics. These data support the conclusion that the absence of deoxycholate in cirrhotic bile is not due to deoxycholate malabsorption. There was also no evidence for the rehydroxylation of deoxycholate in the cirrhotics. Large quantities of lithocholate and deoxycholate were seen in control chromatograms, while these secondary bile acids represented only a small proportion of the total fecal bile acids in the cirrhotic chromatograms; significant amounts of chenodeoxycholate and cholate were seen in addition to trisubstituted ketohydroxy bile acid peaks. Significantly decreased mean amounts of lithocholate (14.1%) and of deoxycholate (15.3%), and significantly increased amounts of chenodeoxycholate (12.1%) and additional secondary bile acids (52.6%), were seen in the cirrhotic patients, in comparison with controls (35.7%, 44.9%, 0.7%, and 17.2%, resp.). A statistically significant increase in fecal cholate excretion was not seen; two cirrhotics without biliary deoxycholate had ample amounts of fecal cholate. *In vitro* fecal inocula from both cirrhotics and controls deconjugated taurocholate. Of the total bile acids extracted from the fecal cultures of the cirrhotics without biliary deoxycholate, 42.1% was 3α,12α-dihydroxy-7-keto-5β-cholanoate, a byproduct of dehydrogenation of the 7-hydroxyl group of cholate; this was seen in only two of eight *in vitro* control incubations. In contrast to controls, there was a large amount of unmetabolized cholate and very littl deoxycholate in chromatograms of bile acids extracted from cirrhotic fecal cultures. The dehydrogenation byproduct was also present in significant quantities in the *in vivo* fecal bile acid extracts of three of four patients without biliary deoxycholate (11.0% of total fecal bile acids). It appears that the marked decrease in 7α-dehydroxylase activit of fecal bacteria of some patients with alcoholic cirrhosis results in impaired conversion of cholate to deoxycholate and explains the lack of biliary deoxycholate in these patients.

7538 GAMMA-GLUTAMYL TRANSPEPTIDASE IN ALCOHOLIC LIVER DISEASES. (Ger.) Ferenci, P.; Dragosics, B.; Pesendorfer, F. X.; Schubert, H. (I. Medizinische Universitatsklinik, Alser Strasse 4, A-1097 Vienna, Austria). *Acta Med. Austriaca* 3(2): 50-54; 1976.

The results of a comparative study of γ-glutamyl transpeptidase (GGT) and other enzymes in alcohol-conditioned and nonalcohol-associated liver disease are presented. The sample populations included 19 cases of steatosis, 7 of fatty livers, and 43 of cirrhosis in the alcohol group, and 28 cases of steatosis and 43 of cirrhosis in the nonalcohol group. GGT was elevated in the steatosis patients of both groups, with a combined average of 102 U/1; BSP retention averaged 10.9%. The transaminases were normal in 7/28 of the nonalcohol group and in 2/19 of the alcohol group. Average steatosis GGT values were 145 U/1 in the alcohol group and 73 U/1 in the nonalcohol group. The GGT/SGPT quotient was 6.9 for the alcohol group and 2.2 for the nonalcohol group. Alkaline phosphatase (AP) was increased only negligibly in 4/28 of the nonalcohol group and 2/19 of the alcohol group, while pseudocholinesterase (PCE) was elevated over 4,000 U/l in a majority of the patients with steatosis not associated with alcohol. In fatty liver conditions, the average GGT was 896 U/l for the alcohol group, while glutamic oxaloacetic transaminase (GOT) was 54 U/l, GPT was 19 U/l, and the GGT/GPT quotient was 53.7. AP was 25% higher than normal in 6/7 of the alcohol group. Among the 86 cirrhotics of both groups, the average enzyme levels in U/l were GGT, 241; GOT, 48; GPT, 30; and AP, 81. The average in U/l for GGT were 334 in the alcohol group and 110 in the nonalcohol group. Average transaminase differences were negligible. In a subgroup of patients with continuing alcohol abuse, the GGT levels averaged 477 U/l in contrast to 68 U/l in a subgroup after a 3-month abstinence. The transaminases and AP were also lower in the abstinent sample. The highest GGT/GPT quotients were found among the continuing alcoholics at 30.7, with 5.9 after 3 months abstinence. Average quotients were 4.5 for 26 postcirrhotics, 3.2 for 13 cases of cryptogenetic cirrhosis, and 24.7 for 4 biliary cirrhotics. Average AP levels in biliary cirrhosis were 10-fold higher than normal. In the alcohol group, 35/43 and 8/43 had average GGT-GPT quotients above and below 5, resp.; in the nonalcohol group, 13/43 and 30/43 had quotients above and below 5, resp. Average values in U/l for alcohol cirrhosis included GGT, 307; GOT, 62; GPT, 31; and AP, 33, with a GGT/GPT quotient of 20.2. Although elevated GGT is not specific for an alcoholic-related condition, the highest levels are found in alcoholics and in cases of cholestasis.

LIVER AND BILIARY TRACT

Cirrhosis

7546 RESPONSES TO TREATMENT CAN DIFFERENTIATE CHRONIC ACTIVE LIVER DISEASE WITH CHOLANGITIC FEATURES FROM THE PRIMARY BILIARY CIRRHOSIS SYNDROME. (Eng.) Geubel, A. P.; Baggenstoss, A. H.; Summerskill, W. H. J. (Mayo Clinic, Foundation and Medical Sch., Rochester, MN). *Gastroenterology* 71(3):444-449; 1976.

The value of response to treatment as an indicator of the correct diagnosis of either chronic active liver disease (CALD) or primary biliary cirrhosis (PBC) syndrome is reported. Of 125 patients fulfilling pre-established criteria for severe CALD and enrolled in a prospective trial of treatment, 15 presented with morphological features consistent with the diagnosis of both CALD and PBC syndrome. Clinical, biochemical, and immunoserological studies failed to distinguish fully between these conditions.

In contrast, the early response to treatment with prednisone and/or azathioprine identified two different groups of patients. Five patients failed to respond, whereas 10 improved, and this was followed by resolution of all clinical, biochemical, and morphological evidence of disease activity. Analysis of the initial chemical findings and cumulative bile duct counts from multiple biopsies correlated failure to respond with biochemical and morphological features more consistent with PBC than CALD. Responses to treatment can therefore be utilized, when indicated, for differentiating CALD with cholangitic features from PBC.

7547 HEPARIN THERAPY IN LIVER CIRRHOSIS. (Ger.) Klein, H.-J.; Falkensammer, Ch.; Gauss, P.; Fischer, M. (Zentrallabor, Krankenhaus Lainz, Wolkersbergenstrasse 1, A-1130 Vienna, Austria). *Acta Med. Austriaca* 2(3):99-100; 1975.

The relation between consumption coagulopathy with or without secondary fibrinolysis and liver parenchymal embarrassment is examined. The clinical sample included 80 patients with liver cirrhosis and signs of coagulopathy. Treatment included administration of 6,000-10,000 IU of depot heparin, divided into 3-4 daily doses. Monitoring was performed at 2-day intervals. Directly after initiation of therapy, the fibrinogen level increased and then normalized within 4 days. After an initial delay, the thrombocyte count increased, and then normalized within 6 days. The normotest increased 35%, but there was little change in the thromboplastin time and thrombin coagulase. Among the 80 patients, 60% had an initially abnormal normotest value that increased by an average of 35% after 8 days of heparin therapy; half of the cases with an abnormal thromboplastin time returned to normal. In the 48% who had had a low fibrinogen level, an increase on the average of 45% (110-210 mg%) was noted 8 days after the initiation of heparin therapy. Thrombin coagulase and thrombocyte counts were normalized in 60-65% of the cases. Thus, heparin amelioration is short-term and pathological levels resume after 14 days.

7548 MANAGEMENT OF GASTROINTESTINAL BLEEDING IN CIRRHOTIC PATIENTS. (Eng.) Rueff, R.; Benhamou, J. P. (No affiliation given). *Clin. Gastroenterol.* 4(2):425-438; 1975.

The current management of gastrointestinal bleeding in cirrhotic patients is discussed. Approximately one-third of patients will stop bleeding without any specific treatment or with gastric ice-water washings only, and for them careful observation is sufficient. Three procedures have been used with comparable results in the treatment of active, moderate bleeding: esophageal tamponade, systemic vasopressin, and selective intraarterial vasopressin. Aggressive treatment (sclerosis of esophageal varices, varix ligation, transesophageal ligation, and emergency portacaval shunt) is indicated in cases of life-threatening hemorrhage. The relative efficacies of these procedures will have to be determined in controlled studies. It is suggested that an *a priori* management strategy be defined for all cirrhotic patients hospitalized for gastrointestinal hemorrhage and that controlled studies be used to verify its value.

7549 CURRENT MANAGEMENT OF ESOPHAGEAL VARICES. (Eng.) Webster, M. W. (Dept. Surgery, Univ. Pittsburgh Sch. Medicine, Pittsburgh, PA 15261). *Surg. Clin. North Am.* 55(2):461-473; 1975.

The pathophysiology, etiology, diagnosis, and treatment of esophageal varices are reviewed, and several surgical techniques for portal decompression are summarized. Endoscopy is the preferred initial step in the evaluation of acute upper gastrointestinal hemorrhage. Selective arteriography is also very useful in its diagnosis and treatment. Splenoportography allows excellent visualization of the portal circulation and is surprisingly safe. Barium contrast studies of the upper gastrointestinal tract continue to be the mainstay of routine investigations, but there are several disadvantages: adequate studies may be difficult in the actively bleeding patient, esophageal varices are frequently not visualized, and there is a high rate of false-negative results in patients with acute gastritis and active peptic ulcer. Evaluation of liver function and percutaneous liver biopsy should be carried out if possible. A fairly standard therapeutic approach to portal hypertension appears to be emerging. In patients with benign extrahepatic portal obstruction, portal decompression by a mesocaval shunt is highly successful, with few complications. Among cirrhotics, only portal decompression currently offers long-term relief from recurrent hemorrhage in patients who have bled. Prophylactic decompression is not indicated in patients who have never bled. Patients with intractable ascites or hypersplenism secondary to portal hypertension rarely require decompression. Intra-arterial infusion of vasopressin has been used successfully to delay the time of decompression and thus improve mortality rates in cases of acute massive upper gastrointestinal bleeding. At present, there is little objective data to favor any particular type of central shunt. Current questions center around patient selection and timing of the procedure. The primary goal is to find ways of avoiding hepatic encephalopathy and the adverse effects of deprivation of portal flow on the liver, through either selective decompression of the variceal bed or portal arterialization. Liver transplantation may ultimately be the answer.

7550 PORTAL SHUNTS. CRITICAL CONSIDERATIONS ON THE SELECTION OF THE SHUNT METHOD. (Ger.) Esser, G. (Chirurgische Klinik, Krankenhaus Maria Hilf, D-405 Monchengladbach 1, Sandradstrasse 43, W. Germany). *Chirurg* 46(9):400-405; 1975.

Conventionally accepted portal shunt surgery for relief of esophageal varice bleeding is reviewed. The following three main classes are listed: portacaval anastomosis (PA), either end-to-end or side-to-side; splenorenal anastomosis (SA), lateral end-to-side; and mesentericocaval anastomosis (MA), side-to-side. The world literature to 1972 shows the surgical mortality to have been 15.8% for PA and 11%

for SA; the 5-yr (and 10-yr) mortality rates were 58.6% (and 89%) for PA and 42% (and 70%) for SA; the number of bleeding recurrences was 10% for PA and 25.8% for SA; and the number of encephalopathies was 16.7% for PA and 11.2% for SA. The author, however, places the incidence of hepatoportal encephalopathy consequent to PA at 27%-35%. The less than favorable survey statistics on lateral SA are said to be unrepresentative since, more than any other intervention, the success of lateral SA depends on the skill and judgment of the surgeon in anticipating the subsequent curvature of the splenic vein. MA is considered standard, though seldom used. Its most favorable prognosis depends on laterolateral anastomosis with the inferior vena cava. More rarely used anastomoses include cavomesenteric, coronariocaval, central splenorenal, omphalocaval, and mesenterirenal. Portacaval shunt with arterialization of the portal vein stump with the hepatic artery, prostheses, or saphenous bypass--the author uses a purely abdominal approach--is not construed as especially valuable, since the incidence of postoperative encephalopathy is high. Central splenorenal anastomosis is most prophylactic of encephalopathy and, because of the low surgical mortality of 7.6% has been adopted as the method of choice.

7551 PORTAL-SYSTEMIC SHUNTS IN PATIENTS WITH CIRRHOSIS. THE NEED OF CONTROLLED CLINICAL TRIALS. (Eng.) Rueff, B.; Maillard, J. N. (Veterans Admin. Hosp., West Haven, CT 06516). *Digestion* 11(5/6):414-427; 1974.

Current indications for portasystemic shunts in cirrhotic patients are reviewed. For patients with intractable ascites, a side-to-side portacaval shunt has been used more frequently than an end-to-side shunt, but there have been no controlled studies comparing the advantages of the two or the treatment results. Prophylactic portacaval shunts have been studied in three controlled trials, and they have been judged to be without benefit. The value of emergency portacaval shunts has been difficult to evaluate because of the high postoperative mortality and the unknown mortality in similar patients who have not been treated surgically. Elective portasystemic shunts significantly decrease the frequency of digestive hemorrhage, but they also significantly increase the frequency of severe hepatic encephalopathy. The factors that should be analyzed in evaluating elective portasystemic shunts include criteria for selection of patients for surgery, the choice of surgical procedure (total portal decompression, end-to-side portacaval shunt and arterialization of the portal vein, partial decompression of the portal system, and selective decompression), the timing of surgery relative to hemorrhage, and the varying techniques of individual surgeons. Because of the lack of controlled clinical trials, the usefulness of portasystemic shunts in patients with cirrhosis and ascites is concluded to be questionable.

7552 CLINICAL-MORPHOLOGICAL EVALUATION OF PORTOGRAPHY IN PATIENTS WITH PORTAL HYPERTENSION SYNDROME. (Rus.) Ershov, Yu. A.; Kiseleva, N. P.; Chubarova, P. V.; Odina, K. M. (All-Union Scientific Res. Inst. Clinical and Experimental Surgery, Moscow, USSR). *Khirurgiia (Mosk.)* (10):67-72; 1975.

Clinical-morphological assessment of splenoportography in 104 patients with different types of portal hypertension is presented. Liver biopsy was performed in all cases at surgery, and additional portography was done in 42 cases. Portal cirrhosis was diagnosed in 28 patients, postnecrotic cirrhosis in 12, mixed cirrhosis in 21, cirrhosis of unknown type in 4, hepatitis in 4, vascular changes (Budd-Chiari syndrome and similar, usually moderate changes) in 24, and cholangitis in 5; the liver was normal in 6 cases. The portal hypertension was found to be intrahepatic in 64 cases, extrahepatic in 20, mixed in 15, and posthepatic in 5 cases. The analysis of the clinical and morphological data indicates that portography permits an assessment of the degree of the vascular decompensation, but not of the structural changes of the hepatic parenchyma in patients with intrahepatic hypertension. In patients with extrahepatic hypertension, portography yields valuable information on the vascular architectonic of the prehepatic segment of the portal vein. The comparison of the portographic and clinical-morphological data shows the absence of specific morphological signs of the different types of blockade of the portal circulation in extrahepatic portal hypertension.

7553 SURGICAL MANAGEMENT OF PORTAL HYPERTENSION. (Eng.) Bengmark, S. (No affiliation given). *Clin. Gastroenterol.* 4(2):395-423; 1975.

Current practices in the management of portal hypertension are reviewed. The two great advantages of classical portasystemic shunts are that they prevent rebleeding and they eliminate ascites in cirrhotic patients. However, the high incidence of hepatic encephalopathy after these procedures constitutes a serious problem. Alternatives to classical portasystemic surgery include selective decompression of the esophageal varices and selective devascularization of the esophagus and upper stomach. Surgical stimulation of the "natural" development of collaterals may contribute to the improvement of surgery. New types of shunt operations include distal splenorenal shunt, left gastric vein-vena cava shunt, side-to-side splenorenal shunt, and interposition mesocaval shunt. The latter appears to be the most suitable for emergency operations. Transposition of the spleen to the s.c. layer has been effective in the rat, and among 10 patients undergoing this procedure, 1 died of heart failure and the other 9 have not rebled during observation periods of 14-25 months. None developed encephalopathy. Acute operation of bleeding varices is undesirable but sometimes necessary. Acute sclerotherapy is a promising alternative to surgery in patients with bleeding esophageal varices. Local decompression by devascularization in bleeding cases appears to produce better results than an acute shunt operation. Prophylactic conventional portacaval shunts offer no advantages, but prophylactic selective decompression remains to be studied. Ascites *per se* is not an indication for a portasystemic shunt. The primary approach to the treatment of encephalopathy is medical, and surgery should be used only in extreme cases.

7554 THE HEPATIC CIRCULATION AND PORTAL HYPERTENSION. (Eng.) Leevy, C. M.; Kiernan, T. (No affiliation given). *Clin. Gastroenterol.* 4(2):381-394; 1975.

The role of pathophysiological abnormalities of hepatic circulation and portal hypertension in the growing morbidity and mortality among patients with liver disease is reviewed, along with diagnostic and therapeutic measures. The principal pathological results of functional and/or structural changes in the vascular bed of the liver are alterations in the metabolism of drugs and foodstuffs, the development of esophageal varices, and decreased oxygenation of the liver cells. Clinical investigations include radiological visualization of the hepatic vascular bed for determination of liver size, the presence of space-occupying lesions, and identification of vessel blockage and collateral or altered flow patterns. In addition, portal pressure and total hepatic and portal blood flow should be determined in all cirrhotic patients with endoscopic evidence of esophageal varices. These data allow more rational decisions regarding medical or surgical management. However, their impact on the morbidity and mortality of patients with advanced portal hypertension has been essentially nil. A significant effect could be realized if the information were applied in the asymptomatic phase of portal hypertension to prevent its progression. Adequate perfusion and oxygenation in the treatment of liver disease and its complications are emphasized. They necessitate the preservation of substrates and enzymes necessary for adequate oxygen supply, avoidance of procedures or therapy that diminish portal or arterial blood flow, and avoidance of injury that would alter the microcirculation or interfere with hepatocyte uptake capacity.

7555 DYNAMIC OF THE TITERS AND TYPES OF ANTIBODIES TO DNA IN DIFFERENT FORMS OF HEPATITIS AND LIVER CIRRHOSIS. (Rus.) Prozorovskaya, N. N.; Baleva, M. P.; Mironova, I. S.; Belokrinitsky, D. V.; Semendyaeva, M. E. (I. M. Sechenov First Moscow Medical Inst., Moscow, USSR). *Sov. Med.* (7): 46-51; 1975.

Dynamic changes in the titers and types of DNA were studied in 43 patients with liver cirrhosis (group 1), in 37 patients with hepatitis (group 2), and in 15 patients with various hepatobiliary diseases (residual viral hepatitis, fatty degeneration, hyperbilirubinemia, cholecystitis, and liver cancer, group 3). Most patients were examined 3-34 times in 1-4 yr, for a total of 365 tests. Antibodies to DNA were not found in five patients in group 1, including patients with portal alcoholic and postnecrotic cirrhosis. Low DNA antibody titers were found in 15 patients with postnecrotic cirrhosis, portal hypertension, and after long-term corticosteroid and cytostatic therapy. The DNA antibody levels decreased in 5, and disappeared in 15 patients in group 1 under therapy. No DNA antibodies were found in eight patients in group 2, low titers were found in three. In group 3, DNA antibodies were found in four patients. The incidences of antibodies of type 1, 2, and 3 were 75, 43, and 5 of 123 tests in group 1, resp.; 123, 34, and 15 of 172 in group 2, resp.; and 3, 1, and 0 of 4 in group 3, resp. Antibodies of types 2 and 3 were predominant during the exacerbation of liver cirrhosis, and type 1 antibodies became prevalent during immunosuppressive therapy. The presence of antibodies to native DNA in the serum of patients exhibiting marked clinical-morphological and highly persistent biochemical activity suggests that antibodies to DNA are a specific indication of destructive changes.

7556 COURSE OF THE PLASMA HISTAMINE CONCENTRATIONS IN THE VENOUS BLOOD AND IN THE PREHEPATIC AND POSTHEPATIC AREAS IN NORMAL SUBJECTS AND IN PATIENTS WITH CIRRHOSIS. (Ger.) Stopik, D.; Beger, H. G.; Hampel, K. E.; Baumgarten, C. (No affiliation given). *Z. Gastroenterol.* 14(Suppl.):236-237; 1976.

The pattern of venous histamine concentrations in chronic progressive liver deficit is reported. The test subjects included 16 patients with unexceptional livers and 11 patients with progressive cirrhosis. Plasma histamine was determined by ion-exchange chromatography and fluorimetry. Plasma histamine in ng/ml for normal subjects was 0.7; for patients with cirrhosis (including those with esophageal varices and portacaval shunt), 1.2; and in patients with fatty liver (I and II), 0.7. The plasma histamine concentrations in cirrhosis was significantly elevated above normal ($p<0.001$); the rate of elimination in cirrhotic patients was significantly lower (41%) than the elimination rate (68%) observed in normal subjects. Participation of elevated plasma histamine levels in hepatogenic gastroduodenal ulcers and in the altered hemodynamics of cirrhosis should be assumed.

7557 EFFECT OF Di-L(+)-ORNITHINE-α-KETOGLUTARIC ACID ON AMMONIA AND LIPID METABOLISM IN PATIENTS WITH CIRRHOSIS AND CONCOMITANT HYPERAMMONEMIA. (Ger.) Leinweber, W.; Goldberg, P.; Erb, W. (Zentrum der Innere Medizin der Universitat, Theodor-Stern-Kai 7, D-6000 Frankfurt/M. 70, W. Germany). *Med. Klin.* 71(24):1043-1046; 1976.

The effect of di-L(+)-ornithine-α-ketoglutaric acid (OKA) on elevated ammonia and lipids in patients with liver cirrhosis is described. The clinical sample consisted of 25 cirrhotics, including 22 with portal hypertension. OKA, 15 g, i.v., was infused during 90 min. The serum triglycerides and cholesterol, in mg%, fell insignificantly from 133 to 114 and 188 to 167, resp. β-Hydroxybutyric acid also decreased from 0.37 to 0.23 mg% and the free fatty acids declined from 854 to 617 mEq/l; both of these changes were significant. Blood sugar was 104-105 mg%; urea was 34-35 mg%. The ammonia level fell from 147 μg% to a normal 111 μg%; this decrease was significant, The outcome of conventional 40 g to 60 g daily therapeutic doses of OKA should be even more effective. The loss in free fatty acids could be explained by an increased breakdown of the free fatty acids, by their increased incorporation into triglycerides, or by inhibition of lipolysis. Only the latter fits the data, but it is not known whether the OKA effect is direct or indirect.

7558 INTESTINAL BACTERIA AND PROTEIN METABOLISM IN HUMAN LIVER CIRRHOSIS.

(Eng.) Muting, D.; Reikowski, H.; Arfeen, N. (Medical Dept., Univ. Hosp., Homburg/Saar, W. Germany). *Am. J. Proctol.* 26(5): 41-50; 1975.

The role of toxic protein metabolites in the development of cirrhosis and hepatic coma was studied in 220 patients with liver cirrhosis. Of these, 102 had no signs of portal hypertension; 118 had severe portal hypertension, 72 in hepatic coma. The blood ammonia level tended to be elevated in patients with hepatic coma, but since it was also normal in some of these patients, other toxic factors were apparently etiologic. *In vitro* experiments indicated that *Escherichia coli* produced the greatest amount of ammonia and free phenols 12 hr after inoculation of nutrient medium, but *Proteus vulgaris* produced the greatest amount after 24 hr. Neither organism produced detectable indican. *E. coli* synthesized p-hydroxyphenylacetic and p-hydroxyphenyllactic acids, and *P. vulgaris* produced p-hydroxyphenyllactic and homovanillic acids. After bleeding from esophageal varices occurs, the highest ammonia level is found at 12-24 hr. In the 39 patients studied, about 50% of the arterial ammonia was detoxified in the brain, as determined by arterial and venous concentrations of ammonia. The amount of ammonia detoxified by the brain was inversely related to the degree of hepatic cirrhosis. There was also a significant difference in inflow and outflow concentrations of free phenols in the brain. In hepatic coma, the concentrations of ammonia and free phenols were the same in arterial and venous blood from the brain. The therapeutic implications of the results include an initially protein-free diet, high enemas to eliminate blood as a source of toxic metabolites, and high doses of neomycin. The latter may be substituted by an oral intake of physiological intestinal bacteria (e.g., *Bacterium bifidum*) or its cofactor (lactulose). Oral feeding of *B. bifidum* milk in 40 cirrhotics reduced blood ammonia and free phenols significantly. Oral lactulose (50 g/day) also significantly decreased blood ammonia and free phenols.

7559 INDIAN CHILDHOOD CIRRHOSIS.

(Eng.) Nayak, N. C.; Ramalingaswami, V. (No affiliation given). *Clin. Gastroenterol.* 4(2):33-349; 1975.

The clinical, pathological, and etiological characteristics of Indian childhood cirrhosis (ICC) are reviewed. The disease is confined almost exclusively to one geographical area and appears to have a familial incidence. The early stage of ICC is characterized by vague gastrointestinal symptomatology, but in the intermediate stage, ascites, abdominal distention, and hepatosplenomegaly are prominent. The advanced stage is accompanied by progressive deterioration in hepatic function and, less commonly, gastrointestinal bleeding or secondary infection. The histopathological findings are described. Hepatocellular hyaline is a frequent and diagnostic morphologic finding. A peculiar lack of regenerative potential accounts for the fatality of ICC, more than the liver cell damage itself. α-Fetoprotein has been identified in 45% of children with ICC, compared to 7% of normal children. Immunoglobulins (Ig), especially IgM, are elevated in the serum. Malnutrition and the defects of carbohydrate and protein metabolism have been eliminated as etiologic factors. The implication of mycotoxin has been suggested by some studies, while in others a viral etiology has been suggested. The hypothesis is advanced that ICC may have a multifactorial basis. It is suggested that this disease probably occurs in the milieu of a functionally immature hepatocyte and is manifest only after the triggering action of an environmental agent, either a toxin or a virus.

7560 ENDOTOXEMIA IN LIVER CIRRHOSIS.

(Ger.) Liehr, H.; Gruen, M.; Brunswig, D.; Sautter, Th. (No affiliation given). *Z. Gastroenterol.* 14 (Suppl.):234-235; 1976.

The frequency and course of endotoxemia in liver cirrhosis is explored. The clinical subjects included 29 cirrhotic patients with evidence of intestinal endotoxins. Endotoxemia (ETX) was already present in 20 patients at the time of hospital admission. In the patients in whom there was no bleeding from esophageal varices (20 patients), functional renal failure (oliguria and retention), encephalopathy, and clotting disturbances related to metabolic disorders were associated with ETX in 67% of the cases and a pyrogenic response (fever or leukocytosis) was concomitant with ETX in 80% of the cases. ETX was found in six patients with bleeding esophageal varices. A coincidence of clotting dysfunction and pyrogenicity occurred in 100%, renal failure in 66%, and encephalopathy in 57% of the ETX patients. ETX must be considered clinically relevant in the pathogenesis of chronic liver disease.

7561 FUNCTIONAL RENAL FAILURE (FRF) IN CIRRHOSIS OF THE LIVER AND LIVER CARCINOMA.

(Eng.) Vesin, P.; Traverso, H. (31 rue de Moscou, 75008 Paris, France). *Postgrad. Med. J.* 51(598):489-491; 1975.

Functional renal failure (FRF) in liver cirrhosis and liver carcinoma, bleeding-induced FRF, and diuretic-induced FRF are discussed, and pertinent literature is reviewed. Bleeding-induced FRF is common following gastrointestinal bleeding. Azotemia and oliguria are the main findings, and refilling the vascular space rapidly leads to regression of azotemia; a significant urine output is evidence of the arrest of bleeding and recovery of renal irrigation. Although the clinical and biological findings in diuretic-induced FRF are similar to those in spontaneous FRF (moderately increased azotemia and creatininemia and moderate hyperkalemia), the prognosis is better in the former entity; functional recovery with increase in the plasma volume and glomerular filtration rate can be achieved following the administration of plasma expanders. In terminal FRF, oliguria, hyponatremia, relative hypovolemia, impairment of the glomerular filtration rate, and impairment of the renal plasma flow are much more conspicuous than in diuretic-induced FRF. The clinical course is usually fatal within weeks or months. In terminal FRF, restoration of the plasma volume is difficult to achieve or maintain and is not accompanied by regression of FRF. A major role of effective plasma volume decrease occurs in the development of terminal FRF. The hemodynamic changes in terminal FRF in patients with primary or metastatic liver carcinoma are similar to those seen in cirrhotic patients with terminal FRF. The differential diagnosis of FRF from chronic nephritis is usually easy. Terminal FRF develops a long time after the initial diagnosis of cirrhosis; oliguria sets in earlier; azotemia is less marked, as are creatininemia and hyperkalemia; and the urea concentration in the urine is higher in FRF than in chronic nephritis. The following modes of treatment in the three types of FRF are recommended, although they are ineffective in most cases of terminal FRF: cessation of diuretic administration; blood volume expansion by means of blood, plasma, plasma expanders (especially human serum albumin deficient in salt), and ascites infusion; water intake restriction; and dietary potassium restriction. Vasodilators or sympathomimetic amines are useless.

7562 THE DEVELOPMENT OF CIRRHOSIS IN WILSON'S DISEASE. (Eng.) Sternlieb, I. (No affiliation given). *Clin. Gastroenterol.* 4(2):367-379; 1975.

The pathogenesis, morphological changes, clinical picture, diagnosis, prognosis, and treatment of Wilson's disease are reviewed. The defect in the biliary excretion of copper in patients with the disease has been localized to the hepatocellular lysozomes. Histological changes in liver biopsy specimens are recognizable long before clinical manifestations are apparent, and the evolution of these changes from steatosis, with fine or large droplets of triglycerides in the hepatocytes, to ultimate cirrhosis is summarized. Symptoms generally appear during adolescence. By the time overt signs or complications of liver disease are present, the pathological process has generally progressed to cirrhosis. The neurological, psychiatric, and ocular manifestations are relatively late developments and are always associated with cirrhosis. The combination of deficiency of serum ceruloplasmin and markedly elevated hepatic copper concentration is diagnostically pathognomonic for Wilson's disease. Untreated, the disease carries a poor prognosis, and the progressively fatal course is characterized by chronic hepatic insufficiency, fulminating hepatic failure, or bleeding from esophageal varices. If therapy is started before the irreversible pathological changes, hepatic function improves in the majority of patients, regardless of the presence of cirrhosis. Bleeding esophageal varices, however, is an ominous sign. Treatment consists of D-penicillamine, 1-2 g/day in divided doses before meals and at bedtime. Major elective surgical procedures should be avoided in these patients. The importance of early diagnosis and institution of treatment is emphasized.

7563 CLINICAL AND EXPERIMENTAL STUDIES ON CIRRHOSIS OF THE LIVER. (Eng.) Okabe, N.; Shimokawa, Y.; Kaneto, A.; Moriyama, M.; Arishima, T.; Jinnouchi, S.; Kuwahara, S.; Saito, H. (Kurume Univ. Sch. Medicine, Kurume, Japan). *Jpn. J. Med.* 13(4):301-302; 1974.

Gallbladder and Biliary Tract Diseases

7572 DISCONNECTION OF THE AMPULLA OF VATER. (Eng.) Corlette, M. B. (Symmes Hosp., Arlington, MA). *Surg. Gynecol. Obstet.* 141(6):915-918; 1975.

A rare case of disconnection of the ampulla of Vater complicating gastric resection is reported, and a discussion of the causes, prevention, and surgery of choice for its reconstruction is presented. The patient, a 62-yr-old man with a long history of duodenal ulcer disease, underwent emergency operation because of bleeding and obstruction. The ulcer penetrating the pancreas was accompanied by marked scarring, but dissection was carried out distal to the ulcer, and the duodenum was closed with no apparent difficulty; a gastrojejunostomy was then constructed. On the 10th postoperative day, he was acidotic, debilitated, and febrile; a fistulogram demonstrated complete disconnection of the papilla of Vater. At reoperation, the papilla of Vater was found projecting from the pancreas, just cephalad to the closed duodenal stump. A Roux-en-Y limb was brought up, and the open end was anastomosed to the pancreatic tissue about the papilla. A silicone rubber tube was brought out through a separate hepaticotomy, and a small silicone catheter was passed through the abdominal wall and the wall of the Roux-en-Y limb and left near, but not transversing, the papilla. The convexity of the limb was allowed to fall loosely near the porta hepatis, so that if stenosis should occur at the papilla, a hepatico-Roux-en-Y jejunostomy would be simple to perform. To lead the bile back through the gastrojejunal anastomosis, a side-to-side Roux-en-Y to afferent jejunal limb anastomosis was performed above a barrier on the Roux-en-Y limb. Healing of all anastomoses occurred without leak. The patient recovered and remains asymptomatic after 10 months.

7573 HEMOBILIA AS A SPECIAL TYPE OF GASTROINTESTINAL BLEEDING. (Ger.) Schildberg, F. W.; Witte, J.; Heberer, G. (Chirurgische Klinik, Univ. Munchen, 8000 Munich 2, Nussbaumstr. 20, W. Germany). *Dtsch. Med. Wochenschr.* 101(19):743-748; 1976.

A retrospect analysis of nine patients with hemobilia (HB) is presented. There were three men, 24-56 yr of age, and six women, 24-66 yr of age. The initial trauma was cholecystectomy 5-6 weeks previous to HB symptoms in two patients. The pathoanatomy was hepatic artery aneurysm or hematoma and the symptomatology included hematemesis (HM), melena (ME), icterus (IC), fever, and pain. Diagnosis was via aortography (AG) or celiacography (CG) and therapy was aneurysm resection with vessel ligation. One patient has survived 18 yr, the other died from postoperative infection. The initial insult in another patient was Billroth II resection, with cholecystectomy and common duct revision. Symptoms included HM and ME; CG found hepatic artery aneurysm, which was resected, with a 7-yr survival. Initial trauma in a fourth case was cholecystectomy, common duct revision, and transduodenal papillotomy; CG revealed a pulsating hepatic artery hematoma after positive HM, ME, IC, fever, and pain. Therapy was aneurysm resection; survival has been 6 yr. Clinical diagnosis of intrahepatic vascular erosion in a patient with ME followed a cicatrix-induced hepatic duct constriction; an 8-yr survival followed conservative treatment. CG diagnosis of intrahepatic bile duct lesions in two febrile patients with ME followed cholecystectomy, common duct revision, and intrahepatic stone removal; both patients are alive 4.5 yr after conservative management. Splenoportography and CG misdiagnosis of intrahepatic aneurysm of the right hepatic artery in a patient with HM, ME, IC, fever, pain, and a ruptured liver was followed by postoperative death from sepsis after hepatic artery ligation. Duodenoscopy and CG diagnosis of intrahepatic vascular erosion in a febrile patient with ME and pain due to chronic calcifying pancreatitis was followed by an 18-month survival after pancreaticojejunostomy and stone removal.

7574 PROBLEMS OF RETAINED CALCULI IN THE BILE DUCT. (Eng.) Sato, T.; Matsushiro, T.; Suzuki, N.; Nakamura, N.; Inoue, S. (Tohoku Univ. Sch. Medicine, Sendai, Japan). *Tohoku J. Exp. Med.* 115(4):367-376; 1975.

A review of 68 cases of second operations for residual or recurrent gallstones is presented. Among these 68 cases, the stones were recurrent in only 4, residual in 38, and uncertain in 26 (apparently residual in most of these). In many of the residual stone cases, previous surgery consisted of cholecystectomy alone, suggesting an insufficient search for residual stones and other abnormalities in the biliary tract during the initial operation. Among the four recurrent stone cases, bile duct stricture, papillary stenosis, and idiopathic choledochus dilatation, occurred in one each; the remaining case, although free of any sign of bile stasis, had a gallstone formed around a silk-thread core. Indications for additional sphincteroplasty and biliodigestive anastomosis in second operations were strictly consistent with those in the first operations. There were seven operative mortalities after the second operation, and most of these were associated with persistent gallstones of long duration and serious hepatic failure. Follow-up studies in 53 patients, ranging in age from 2 months to 8 yr 10 months, revealed that 51 were in good health without any particular complaints. These results suggest that retained gallstone cases should be referred for surgical treatment as soon as possible.

7575 TREATMENT OF CHOLECYSTITIS: CHOLECYSTOSTOMY OR CHOLECYSTECTOMY? (Eng.) Vuori, E. E. (Loimaa District Hosp., Loimaa, Finland 32200). *Am. J. Surg.* 132(1):75-80; 1976.

A review of 992 consecutive patients treated by cholecystectomy for cholelithiasis and cholecystitis is presented. These patients were divided into four groups according to the gross pathoanatomic condition at the time of surgery: 454 cases of simple cholelithiasis (group I); 230 cases of acute inflammation (group II), including 98 cases that had reached the necrotic stage (group IIb); and 308 cases of chronic inflammation (group III). The mean ages of these groups were 46 yr, 3 months; 55 yr; 55 yr, 9 months; and 51 yr, 4 months; resp. The incidence of operative technical complications was 1.1, 4.3, 6.1, and 4.5%, resp. Corresponding postoperative complications occurred at incidences of 2.0, 5.2, 8.2, and 3.2%, resp. The percentages of deaths in these groups were 0.2, 0.9, 1.0, and 0.6%, resp. Operative technical complications included ruptured cystic ducts, perforated choledochal ducts, perforated cystic ducts, and ruptured minor hepatic ducts. Nonfatal postoperative complications included: pulmonary embolus, pneumonia, pleuritis of the serosa, purulent peritonitis, partial wound rupture with purulent peritonitis and paralytic ileus, wound infection, acute pyelonephritis, diarrhea, and thrombophlebitis cruris. Fatal postoperative complications included pulmonary embolus, myocardial infarction, pneumonia and myocardial infarction, and ruptured cerebral aneurysm. The low incidences of intraoperative technical difficulties and postoperative nonfatal complications, as well as the unusually low mortality (0.5% in the entire series and 0.7% among those with cholecystitis), suggest that cholecystectomy is the preferred therapy for cholecystitis at all stages of the disease, when all coexisting diseases and water and electrolyte imbalances have been treated.

7576 NONSURGICAL TREATMENT OF POSTOPERATIVELY RETAINED STONES IN THE EXTRAHEPATIC BILE DUCTS.

(Ger.) Szalatnay, Z.; Moehr, P.; Akovbiantz, A. (Chirurgische Klinik des Stadtspitals Waid, Zurich, Switzerland). *Schweiz. Med. Wochenschr.* 106(26):876-880; 1976.

The use of sodium cholate (SC) dissolution of postoperatively retained stones is described. A 71-yr-old man was cholecystectomized after persistent epigastric pain. Peroperative cholangiography showed a suspicious shadow at the level of the hepatic duct bifurcation. During common bile duct revision, a large stone from the bifurcation area and several smaller stones from the papillary region were removed. The suspicious finding at the left bifurcation remained, but was considered an artifact; sphincterotomy was not performed. Postoperative recovery was uneventful, but T-drain cholangiography continued to show contrast media deficit at the bifurcation. A 22-day SC perfusion was undertaken via T-drain and followed cholangiographically every 3-5 days. The patient experienced slight diarrhea, managed by cholestyramine (18 g/day, p.o.), but no other complication appeared after radiological disappearance of the stone. The indications for perfusion include a stone composition of at least 70% cholesterol (the patient's was 100%), a basically unhindered bile duct flow, and sufficient T-drainage density relative to the free abdominal cavity. Central venous pressure should not exceed 30 cm (water column). The infusion solution includes 60 ml of 100 mM of SC in physiological salt solution perfused via T-drain for 2 hr daily for 3-14 days or longer. Relevant literature is reviewed, and the technique is recommended as a preferred alternative to reintervention.

7577 NONOPERATIVE EXTRACTION OF STONES FROM THE BILE DUCTS.

(Eng.) Burhenne, H. J. (Children's Hosp., P.O. Box 3805, San Francisco, CA 94119). *Semin. Roentgenol.* 11(3):213-217; 1976.

A procedure for the nonoperative extraction of retained biliary tract stones observed after cholecystectomy is described. About 5 weeks after cholecystectomy, another T-tube cholangiogram is obtained to assure that the retained stones have not shifted position or passed into the duodenum. After the T-tube has been removed, a steerable catheter is introduced through the sinus tract, and the catheter tip is manipulated into the common duct. The steerable catheter is positioned with its tip just beyond the location of the retained stone. A stone basket is introduced through the catheter, positioned distal to the stone, and then opened. The open basket is withdrawn in an attempt to snare the retained stone. Several passes may be required to accomplish this. A turning twist of the wire stem of the basket may be required to engage the stone. The basket is only retracted, never advanced, outside the enclosure of the steerable catheter. The stone is extracted through the drain tract. In order to facilitate the nonoperative extraction of retained stones, it is recommended that surgeons use no less than a number 14 French T-tube routinely after choledochotomy. Among 217 patients undergoing this procedure, 95% had successful extraction. No fatalities occurred.

7578 INSTRUCTIONS FOR THE DISSOLUTION OF CHOLESTEROL GALLSTONES WITH CHENODEOXYCHOLIC ACID. RECOMMENDATIONS OF THE PARTICIPANTS IN THE WORKSHOP "MEDICINAL DISSOLUTION OF GALLSTONES," HELD IN VIENNA, SEPT. 25, 1975.

(Ger.) Leuschner, U. (Zentrum der Inneren Medizin der Universitat, 6000 Frankfurt/Main, Theodor-Stern-Kai 7, W. Germany). *Dtsch. Med. Wochenschr.* 101(30):1132-1133; 1976.

Indications, contraindications, and therapeutic guidelines for chenodeoxycholic acid dissolution (CAD) of cholesterol stones are summarized. The principal indication is a gallbladder with functional integrity. Patients with nonopaque ductal stones can be treated if CAD is the only therapeutic alternative. Some contraindications are calcified stones, bilirubin deposits, stone diameters over 2 cm, acute cholecystitis, cholestasis, hepatitis, liver cirrhosis, alcoholic fatty liver hepatitis, acute gastritis, florid gastrointestinal ulcers, chronic bowel inflammation, malabsorption syndrome, bile acid diarrhea, cholestyramine therapy, pregnancy, and renal failure or retention. The mean daily dose should total 15 mg/kg for at least 2 yr. Monitoring, both prior to therapy initiation and during the course, should include SGOT or SGPT, alkaline phosphatase, bilirubin, gamma-glutamyl transpeptidase, cholesterol, oral cholecystography, liver biopsy, and (optional) determination of the lithogenic index, every 6-8 weeks, and 3 and 6 months. Management of complications include dose reduction to 250 mg/day for diarrhea and persistent transaminase or alkaline phosphatase elevation to or above twice the normal limit and cholecystectomy for increasing incidence of gallbladder pain.

7579 ACUTE CHOLECYSTITIS AS A POSTOPERATIVE COMPLICATION. (Eng.) Ottinger, L. W. (275 Charles St., Boston, MA 02114). *Ann. Surg.* 184(2):162-165; 1976.

The clinical course and management of 40 patients who underwent surgery for acute cholecystitis, which developed as a complication of nonbiliary surgery, are reviewed. Twenty-nine patients developed cholecystitis following their first operation, 11 had had two operations. In 22 patients, an unexplained fever was the first sign of cholecystitis. Only 11 presented with typical symptoms: pain and upper gastrointestinal complaints. Fifteen patients had cholecystitis alone, but 25 had an additional complication of gangrene, perforation, empyema, or cholangitis. In 14 patients, there were no stones in either the gallbladder or the common duct. In the 26 patients with cholelithiasis, 18 had a complication of cholecystitis. Common duct stones were present in six patients. Overall mortality was 47%. In 27%, the death could be directly attributed to the biliary complication. Of the 13 patients with perforation, empyema, or cholangitis, only 2 recovered. The cause of death in almost every case was sepsis. Bile stasis leading to concentration and inspissation of the gallbladder contents and obstruction to outflow, either from stones or the inspissated gallbladder contents, have been proposed as causes. It is concluded that the diagnosis of acute cholecystitis depends almost exclusively on the findings on physical examination and that immediate surgery is the best course for the postoperative patient.

7580 ACUTE CHOLECYSTITIS. (Eng.) Glenn, F. (No affiliation given). *Surg. Gynecol. Obstet.* 143(1):56-60; 1976.

A review of 2,021 patients treated surgically for acute cholecystitis over a 42-yr period is presented. Cholecystectomy, without prolonged delay after the demonstration of calculous disease of the biliary tract, was the treatment of choice, and the overall mortality rate for this group of patients was 3.4%. A total of 1,445 patients underwent cholecystectomy alone, while in 283 patients, common duct exploration was combined with cholecystectomy. Cholecystostomy alone was done in 283 patients as a lesser procedure than cholecystectomy, and in 10 additional patients, common duct exploration was done as well. The high mortality of the 503 patients who were 65 yr of age or older (9.3%), in contrast to a mortality rate of 1.4% for 1,518 patients under the age of 65 yr, reflects the limited capacity of the elderly to withstand surgical procedures. It is also indicative of the significance of long-standing disease of the biliary tract.

7581 THE EFFECT OF LOSS OF GALLBLADDER FUNCTION ON BILIARY LIPID COMPOSITION IN SUBJECTS WITH CHOLESTEROL GALLSTONES. (Eng.) Redinger, R. N. (Univ. Hosp., Univ. Western Ontario, London, Ontario, Canada). *Gastroenterology* 71(3):470-474; 1976.

The changes in biliary lipid composition were followed in five subjects with asymptomatic cholesterol cholelithiasis until they developed nonfunctioning gallbladders. No significant changes were noted in the relative proportion of phospholipid. There was a significant increase in the mean level of bile salt (BS, 65.5 versus 76.3 mol%, $p<0.05$) and a decrease in cholesterol (9.73 versus 5.58 mol%, $p<0.05$). The sediment crystal load also decreased after development of gallbladder nonfunction, whereas no crystals were seen in three other patients following cholecystectomy. This suggests that gallbladder contractibility had decreased in the patients with nonfunctioning gallbladders and/or that fewer cholesterol crystals were being formed in their bile. In the three postcholecystectomy subjects' bile, the increase in the relative proportion of BS did not reach statistical significance compared to bile composition from subjects with functioning gallbladders and gallstones (72.1 versus 65 mol%, $p<0.1$, >0.05), but that of cholesterol did (8.68 versus 4.23 mol%, $p<0.05$). A significant increase in secondary bile acids was found in subjects with nonfunctioning gallbladders, which persisted after cholecystectomy (16.2 versus 29.0 mol%, $p<0.05$). In the three patients with cholecystectomy, all stones were of the cholesterol type. The results support the hypothesis that gallbladder function plays an active role in determining biliary lipid composition.

7582 CHOLEDOCHAL CYSTS: ROENTGENOGRAPHIC TECHNIQUES. (Eng.) Rosenfield, N.; Griscom, N. T. (Dept. Radiology, Beth Israel Hosp., Boston, MA 02215). *Radiology* 114(1):113-120; 1975.

A series of 24 cases of choledochal cysts seen over the last 25 yr is presented. Nine patients were less than 1 yr of age and the oldest was 14 yr; five were boys. The classification triad of jaundice, pain, and mass was present in only one patient, although all had at least one of these symtpoms. Only seven cases were definitively diagnosed preoperatively: three by ^{131}I-rose bengal scanning, two by i.v. cholangiography, and one each by oral cholecystography and ^{99m}Tc-sulfur colloid scanning followed by angiography. In general, the upper gastrointestinal series examination yielded the greatest percentage of positive examinations (84%); the highest incidence of definitive positive examinations (3/4) was found with the ^{131}I-rose bengal scan. All 24 cysts were the type 1 of Alonso-lej (cystic dilatation of the common duct). Associated congenital anomalies were rare, and stones, cirrhosis, and pancreatitis were occasionally encountered. The treatment consists of surgical drainage: 15 had cystic drainage into the duodenum, 6 underwent anastomosis to the jejunum, and 3 had subtotal cyst excision before a Roux-en-Y loop was created. Twenty-one surviving patients were followed for 1-19 yr: 18 were sympton-free, 2 had recurrent jaundice, and 1 had chronic pancreatitis. There were two postoperative deaths, both from overwhelming sepsis.

7583 CEROID-LIKE HISTIOCYTIC GRANULOMA OF GALL-BLADDER—A PREVIOUSLY UNDESCRIBED LESION. (Eng.) Takahashi, K.; Oka, K.; Hakozaki, H.; Kojima, M. (Fukushima Medical Coll., Fukushima, Japan). *Acta Pathol. Jpn.* 26(1):25-46; 1976.

A peculiar gallbladder granuloma, characterized by marked proliferation of ceroid-filled brown histiocytes, was pathomorphologically, histochemically, and ultrastructurally examined in 13 cases to define the pathologic features of this previously undescribed lesion. The lesion grossly showed a granulomatous appearance of yellow-brown to dark brown color, and developed in the wall of the gallbladder. They developed from the submucosal layer to the mucosal layer, cholesterol crystal clefts, and empty vacuoles. Histologically, there was a proliferation of histiocytes containing abundant brown pigment granules in their cytoplasm. The pigment granules demonstrated staining characteristics closely resembling those of lipogenic ceroid-like pigment. The granules found in the proliferating histocytes showed prominent sudanophilia in paraffin sections and positive reaction of the mercuric diphenylcarbazone method. Ultrastructurally, these granules showed amorphus osmiophilic inclusions of heterogenous material, lamellar myelin-like structures, and some extended to and connected with the mucous membrane. Most lesions developed in isolation, although one case had two lesions. Lipid components of the bile juice, particularly unsaturated fatty acids and phospholipids, are suggested to play a major role in the development of ceroid-like histiocytic granuloma of the gallbladder.

7584 LESIONS OF THE SEGMENTAL AND LOBAR HEPATIC DUCTS. (Eng.) Longmire, W. P., Jr.; Tompkins, R. K. (Dept. Surgery, UCLA Sch. Medicine, Los Angeles, CA 90024). *Ann. Surg.* 182(4):478-495; 1975.

The hepatic and systemic effects of segmental or hepatic bile duct injury, with or without infection, congenital hepatic duct lesions, intrahepatic stones, and hepatic duct carcinoma and their effective management are discussed. These lesions produce, singly or in combination, obstruction to bile flow, precipitation of particulate matter and formation of stones, development of infection, or external biliary fistula. Unless an unobstructed uninfected biliary flow can be achieved through a segmental or lobar duct, it is better that the duct be completely obstructed and the affected liver parenchyma allowed to atrophy, provided there is normal biliary flow from the residual 50% of liver. This concept is important in the management of injured segmental or lobar hepatic ducts and in the palliative treatment of bile duct carcinoma. Localized intrahepatic infections communicating with abnormal biliary ducts require hepatic resection of the infected parenchyma and ducts for cure. The abnormality may be saccular dilatation of the intrahepatic ductal system, with abscess formation, or intrahepatic abscess associated with stenosis of the ductal system from trauma to the duct, to the duct and liver, or to retained intrahepatic stones. Diffusely situated intrahepatic abscesses secondary to ductal abnormalities can be treated with systemic antibiotics. local drainage of a dominant abscess, and efforts to improve biliary drainage. Case reports illustrating these concepts are included.

7585 BILIARY OBSTRUCTION IN THE NEWBORN. (Eng.) Koop, C. E. (Children's Hosp. Philadelphia, 34th St. and Civic Center Blvd., Philadelphia, PA 19104). *Surg. Clin. North Am.* 56(2):373-377; 1976.

Biliary obstructive lesions that require management in the early months of life by pediatric surgeons are identified. The first is extrahepatic discontinuity of the biliary tree, which is due to a developmental accident. The liver shows the same histologic picture as that of an acquired obstruction in the older infant or child. These lesions are correctable. In biliary hypoplasia, the ducts range from smaller than normal to microscopic in size. The hepatic histology shows variation in the severity of cirrhosis and ductal proliferation. This can be treated by Kasai's operation, or a period of observance, perhaps accompanied by steroid therapy, may be implemented. In some cases, if there is no loss of jaundice in 3-4 weeks, reexploration and the operation seem indicated. In some cases, there are no extrahepatic ducts visible to the naked eye. Some may have microscopic lumina in the biliary cords and will respond to the Kasai operation. Other patients will not have ducts, even under microscopic investigation, but they may still benefit from Kasai's operation.

7608 POLYVINYL ALCOHOL (IVALON)--A NEW EMBOLIC MATERIAL.

(Eng.) Tadavarthy, S. M.; Moller, J. H.; Amplatz, K. (Univ. Minnesota Hosps., Minneapolis, MN 55455). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 125(3):609-616; 1975.

Experience with the use of polyvinyl alcohol, both in dogs and in two patients, is reported, together with a description of the previous uses of this substance and of the preparation of polyvinyl alcohol emboli. The polyvinyl alcohol plastic foam is soaked in heparin and compressed in a vice and dried. One-half- to one-millimeter diameter plugs are cut from the material and preloaded in small plastic tubing. The plugs and tubing are then gas sterilized. At the time of embolization. the preloaded tubes are connected to a catheter, and the plugs are flushed into the catheter and blood vessel by forceful manual saline injection. Seventy-two hours following the embolization of the renal arteries in dogs, angiography revealed obstruction of the artery with no evidence of recanalization. One week after the procedure, the renal artery was occluded at its most proximal portion due to antegrade thrombosis. Histologic examination of the renal cortex revealed thrombosis of several renal arteries, noncanalization, and several areas of hemorrhagic necrosis due to thrombosis of the intrarenal arteries. The problem of lysis and fragmentation does not exist. In one case, the contralateral kidney showed several areas of infarction, and this was thought to be due to too rapid injection of the emboli. Transcatheter embolization of the hepatic artery was carried out in a 4.5-yr-old boy with a hemangioendothelioma to decrease the size of the liver in preparation for a liver transplant. Because the artery was huge, injection of small emboli could not be used. A stainless steel umbrella and small nylon bristle brushes were advanced with a guidewire through the catheter, serving as a baffle for the injected embolic material. After the procedure, there was practically no blood flow through the embolized hepatic artery, and complete occlusion at its origin, with demonstration of collateral flow to the liver via branches arising directly from the aorta and inferior phrenic arteries, was seen 2 months later. The patient died of metastatic hemangiosarcoma; autopsy revealed no distal embolization due to the baffle and antegrade thrombosis of the main hepatic artery. A second patient had congestive heart failure complicating a large hemangioendothelioma on the neck and forehead. The heart failure was thought to be due to high output failure, and embolization was used to decrease the vascular supply to the mass. Feeders from the left and right thyrocervical trunk, from the right and left subclavian artery, and from the left occipital artery were embolized, and temporary clinical relief was seen. Polyvinyl alcohol has proved to be a good synthetic embolic material.

7609 INFLUENCE OF THE POSTOPERATIVE STATE ON THE INTRACELLULAR FREE AMINO ACIDS IN HUMAN MUSCLE TISSUE.

(Eng.) Vinnars, E.; Bergstom, J.; Furst, P. (Dept. Anesthesiology, Sit Eriks sjukhus, S-112 82 Stockholm, Sweden). *Ann. Surg.* 182(6): 665-671; 1975.

The free amino acid concentrations in muscle tissue were determined in five patients before and 2-3 days after major, uncomplicated abdominal surgery. Muscle tissue was obtained by needle biopsy from the lateral portion of the quadriceps femoris, and plasma free amino acids were measured. Most of the amino acids showed much higher concentration in intracellular water than in plasma. Preoperatively, all amino acids examined were formed within normal limits. Postoperatively, the total amount of free amino acids in plasma and muscle was decreased, and the amino acid profiles differed from those of normal subjects. In post-traumatic plasma, the most significant changes were an increase in phenylalanine and tyrosine and a decrease in isoleucine and histidine ($p<0.001$). In muscle, the greatest decrease occurred in the concentrations of glutamine, arginine, and lysine, followed by proline and glutamic acid. The increases in taurine, valine, and phenylalanine were all highly significant, and those in serine, glycine, alanine, and leucine were significant. There were marked increases (compared with normal values) in the gradient between the intracellular and plasma concentrations that were highly significant for glycine and valine and significant for serine, alanine, isoleucine, and leucine. The phenylalanine/tyrosine ratio was increased in both plasma and muscle, but was significant only for muscle. These studies confirm that the alterations in muscle-free amino acids are not reflected in the plasma amino acid concentrations.

7610 ANTIBIOTIC RESISTANCE AND SURVIVAL OF E Coli IN THE ALIMENTARY TRACT.

(Eng.) Hartley, C. L.; Richmond, M. H. (Dept. Bacteriology, Univ. Bristol., Bristol BS8 1TD, England). *Br. Med. J.* 4(5988):71-74; 1975.

The survival of various resistant and sensitive *Escherichia coli* O types in the alimentary tract of persons not known to be receiving antibiotics as studied to determine why some resistant strains persist in persons not undergoing antibiotic treatment. Factors that are important for the survival of resistant strains during the transition from an antibiotic-rich to an antibiotic-poor (or antibiotic-free) environment in man were also studied. Fecal samples were taken on a routine basis at intervals of a few days from volunteers, and plated bacterial colonies were tested with discs for their resistance to ampicillin (25 μg/disc), tetracycline (50 μg), streptomycin (25 μg), and chloramphenicol (50 μg). The colonies were also O-typed. When isolates were resistant to antibiotics, the transfer of their resistance determinants to an R-negative *E. coli* recipient was tested by a standard mating procedure. The incidence of both resistant and sensitive *E. coli* O types in the predominant part of the coliform flora was followed in 33 persons for a total of 2,578 days. Ninety-five different sensitive and 65 different resistant O-types were found. The mean residence time of all sensitive O types was 5.7 days, while that for resistant strains was 6.1 days. When this second average was recalculated for those coliforms carrying R factors alone (as shown either by resistance transfer in the standard test or by the presence of a tetracycline resistance determinant in the strain), the mean residence time for R-positive O types was 6.6 days. R-factor carriage does not seem to have a major effect on the survival of *E. coli* strains, as identified by O-typing in persons not receiving antibiotics. Survival of resistant bacteria in the absence of antibiotic selection pressure appears to depend on the characteristics of the *E. coli* host rather than on those of the plasmid that is carried.

7611 INTESTINAL BEHCET'S DISEASE: REPORT OF FIVE CASES. (Eng.) Baba, S.; Maruta, M.; Ando, K.; Teramoto, T.; Endo, I. (Keio Univ. Sch. Medicine, 35 Shinanomachi, Shinjuku-ku, Tokyo, Japan). *Dis. Colon Rectum* 19(5):428-440; 1976.
